# Winning the Oil Endgame

*Innovation for  
Profits,  
Jobs,  
and  
Security*

Amory B. Lovins,  
E. Kyle Datta,  
Odd-Even Bustnes, Jonathan G. Koomey, and Nathan J. Glasgow

*Forewords by George P. Shultz and  
Sir Mark Moody-Stuart*

Over the next few decades,  
the United States can get  
completely off oil *and*  
revitalize its economy—led  
by business for profit

US 2025 CO<sub>2</sub> emissions  
would drop 26% as a free  
byproduct of the profitable  
oil savings

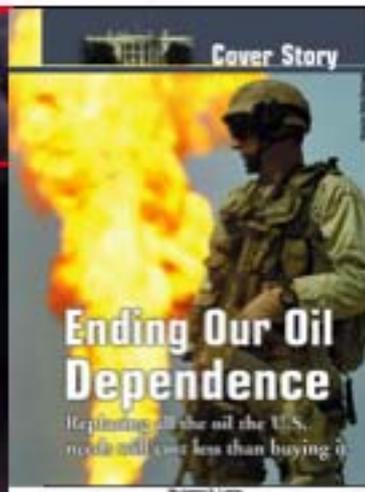

POLITICS & POLICY

# Unlikely Allies Fight U.S. Oil Dependence

*Bipartisan Network to Press for Reduced Consumption, Quicker Development of New Fuels*

Wall St. J., 28 March 2005

FT, Asian edn., p. 1,  
12/13 March 2005

WEEKEND

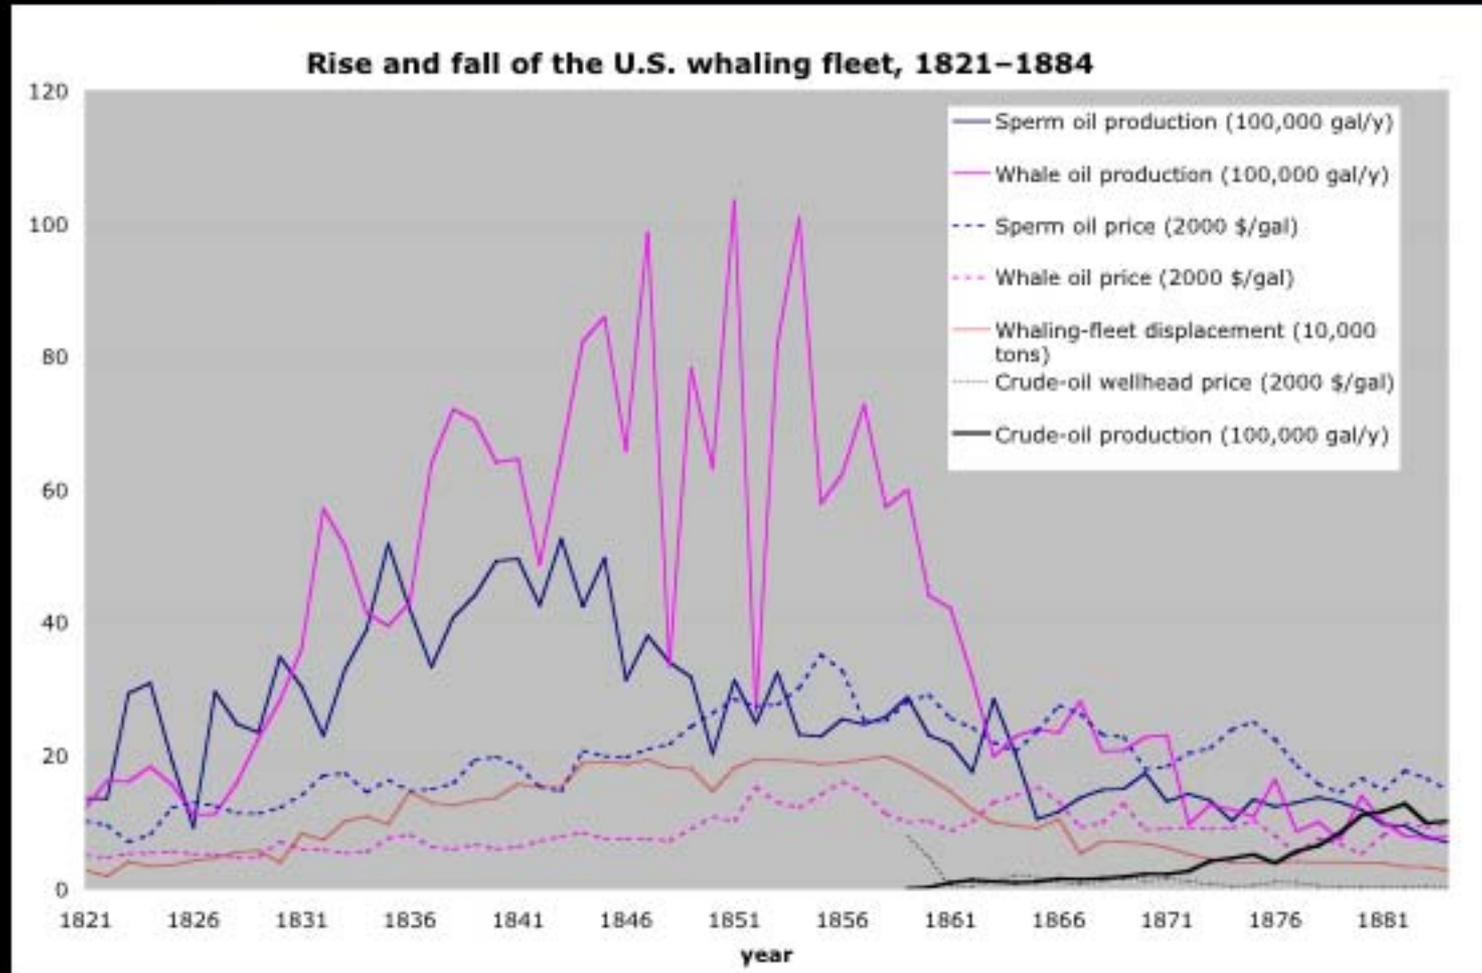

FINANCIAL TIMES

**IEA says world must turn away from oil**

■ Agency says governments should act to cut demand

# Whalers ran out of customers before they ran out of whales...

**...even before Drake struck oil in 1859!**

# Winning the Game: restoring competitiveness *and* eliminating oil dependence

- ▶ **National security *and* national competitiveness at risk**

## Why should we care?

- ▶ **Oil insecurity, geopolitical rivalry, price volatility, perhaps depletion, climatic stability,...**
- ▶ **Japan, EU, China will eat Detroit for lunch; Airbus has overtaken Boeing; core sectors are at risk; the U.S. choice**

## How do we win?

1. **Efficient end-use can save half the oil @ \$12/bbl (2000 \$)**
  2. **Biofuels can replace another fifth**
  3. **Saved gas can displace the rest**
- } **av. cost \$18/bbl**
- Vs. EIA's forecast \$26/bbl in 2025, save net \$70 billion a year**

## How do we capture this prize?

- ▶ Invest \$90 billion in transportation equipment industries, plus...

- ▶ \$90 billion to build an advanced biofuels industry

- ▶ Business should lead, but...

- ▶ ...needs acceleration, while...

- ▶ ...expanding customer choice and reducing business risks

- ▶ Federal government: lead, follow, or get out of the way

- ▶ Creates 1 million good new American jobs (3/4 rural)

- ▶ Preserves 1 million jobs

- ▶ Returns >\$150 billion/year

- ▶ Support, not distort, business logic with new policies...

- ▶ Market-oriented without taxes

- ▶ Innovation-driven without mandates

- ▶ Reduce federal deficit

- ▶ Broad political appeal

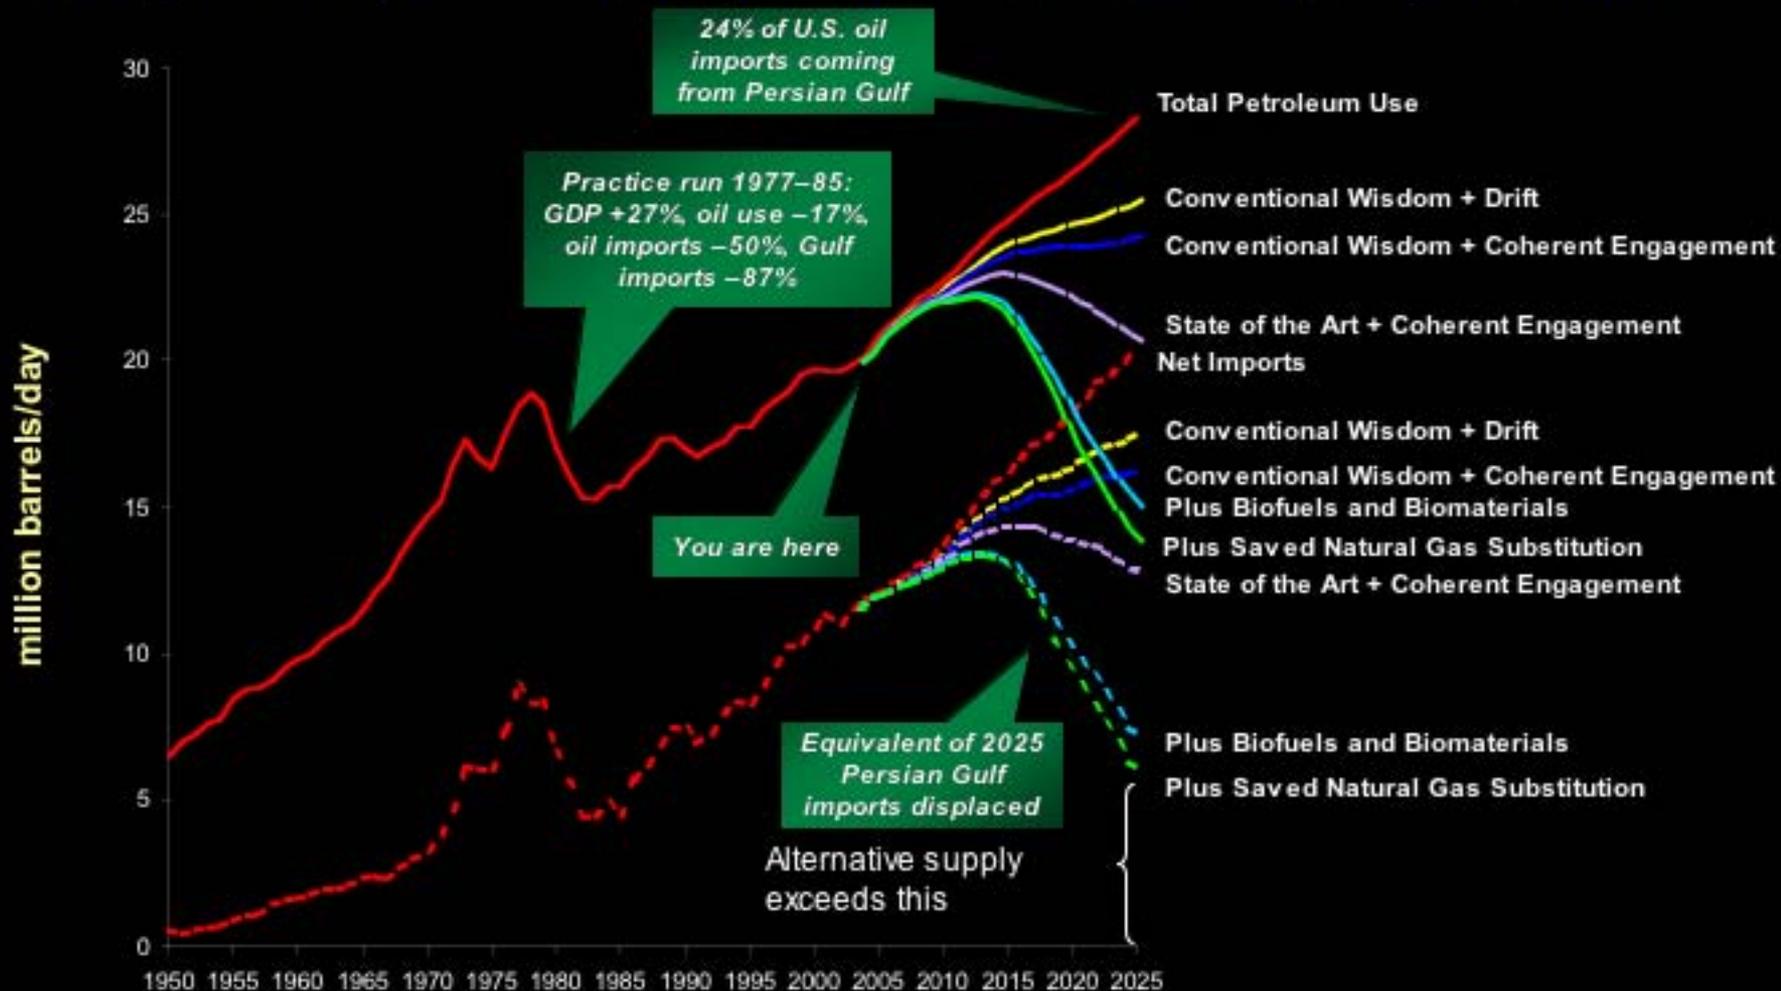

- ▶ Needs little or no Congressional action

- ▶ Can be administrative, or done by the states

# The energy future is choice, not fate

## U.S. petroleum product consumption and net petroleum imports, 1950–2025

# Cars and light trucks: save 69% of EIA 2025 fuel at an av. cost of 57¢/gallon

Ultralight (e.g. carbon composites), low drag, hybrid

GM *Ultralite* 1991, 5 seats, 0-60mph/7.3s, 84 mpg, nonhybrid

Opel *Eco-Speedster* 2002, 2 seats, 155 mph, 94 mpg, diesel hybrid

Toyota *Allessandro Volta* 2004, 3 seats abreast, 408 hp, 0-60/<4 s, 32 mpg

Hypercar *Revolution* 2000 virtual design, 5 seats, midsize SUV, 66 mpg gasoline hybrid w/3-y payback, 0-60/7.1 s), 114 mpg w/H<sub>2</sub>

*Surprise: 2x-mpg ultralighting is free, because the costlier materials are offset by cheaper automaking and smaller propulsion system*

## Heavy trucks: save 25% free, 65% @ 25¢/gallon

Better aero & tires, better engines etc., less weight

PACCAR high-eff. concept truck

Colani/Spitzer tanker (Europe), reportedly 11.25 mpg

Two recent concept trucks

6.2 to 11.8 mpg with 60% IRR by improving aero drag, tires, engines, mass, driveline, acces. loads & APU; then ~16 mpg via operational improvements; being built 2005

Big haulers' margins double from 3% to 6–7%...so create demand pull — currently underway, led by major customers

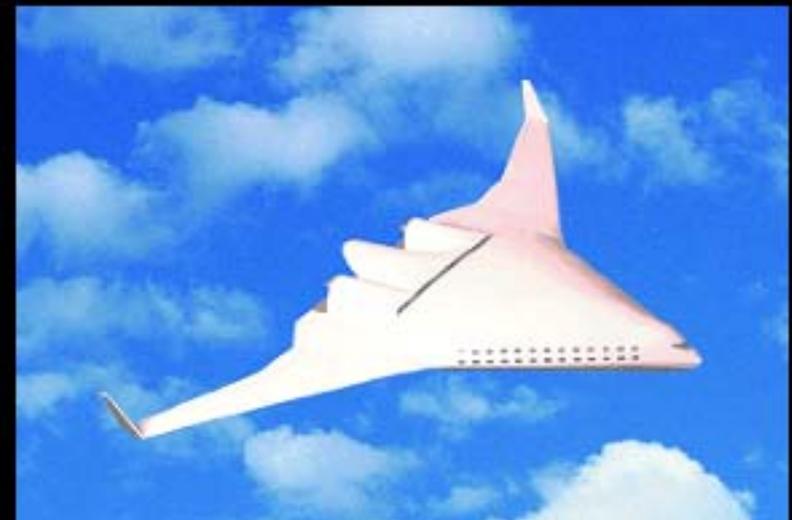

## Planes: cost-effectively double or triple efficiency

Save 20% ~ free (787, 2007)

...then, ~2015–20, save 45% @ 46¢/gal; with blended-wing-body & internal engines, ~65% at comparable or lower cost, via lighter weight, better engines & aerodynamics

## Light vehicles: challenging a basic Detroit and Washington assumption

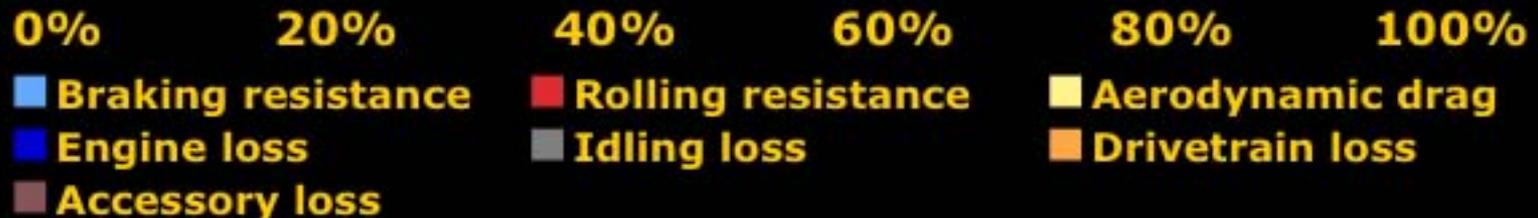

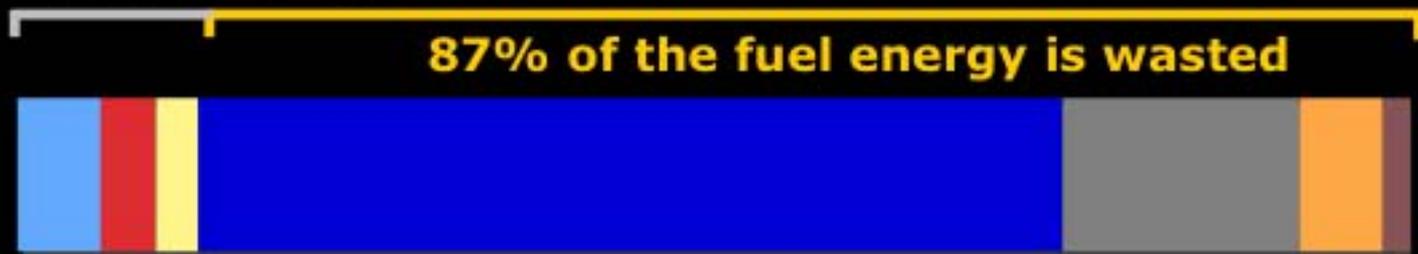

---

- ◇ Efficiency assumed to be a tradeoff against price, size, performance, safety,...
- ◇ Hence policy intervention needed to induce customers to buy the compromised vehicles; but Congress has gridlocked on that for >20 years
- ◇ But what if superefficiency were a byproduct of breakthrough engineering, so people would buy the cars because they're *better*—like buying digital media instead of vinyl phonograph records?
- ◇ An engineering end-run around tax/CAFE gridlock
- ◇ Robust business model based solely on value to customer and competitive advantage to maker

# Where does a car's gasoline go?

13% tractive load

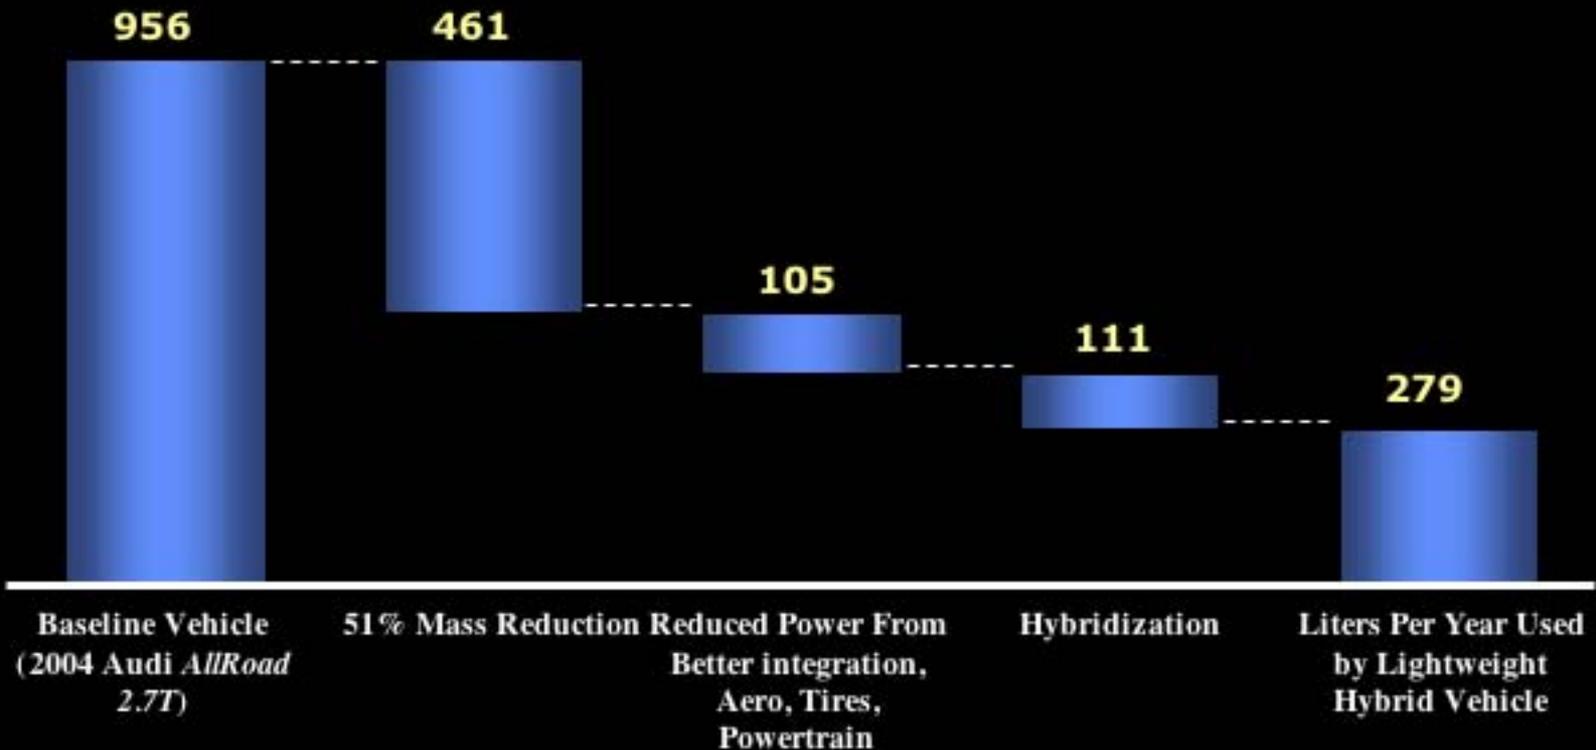

- 6% accelerates the car, <1% moves the driver
- Three-fourths of the fuel use is weight-related
- Each unit of energy saved at the wheels saves ~7–8 units of gasoline in the tank (or ~3–4 with a hybrid)
- **So first make the car radically lighter!**

# Critical insight: light weight *before* aerodynamics and powertrain creates **68% of SUV fuel savings (hybrid: 16%)**

U.S. gallons per year in typical U.S. driving pattern

Means: light metals, composites, ultralight steels

Issues: crashworthiness and manufacturing cost

## Three technology paths: aluminum, light steels, carbon composites (the strongest & lightest)

- Immaterial damage when T-boned by *Golf*
- 15 lb of carbon crush cones (0.4% of car's weight) can absorb all crash energy @ 66 mph

- **Carbon-composite crush structures can absorb 6–12 $\times$  as much energy per pound as steel**
- **This can make cars lighter *but bigger and safer... and simpler and potentially cheaper to manufacture***

## Migrating innovation from military aerospace to civilian cars

◇ At the Lockheed Martin Skunk Works<sup>®</sup>, engineer David Taggart led a '94–96 team\* that designed an advanced tactical fighter-plane airframe...

- made 95% of carbon-fiber composites
- 1/3 lighter than its 72%-metal predecessor
- *but 2/3 cheaper...*
- because it was designed for optimal manufacturing from composites, not from metal

\*Integrated Technology for Affordability (IATA)

◇ Finding no military customer for something so radical, he left. I soon hired him to lead the 2000 design of an halved-weight SUV with two Tier Ones, *Intl. J. Veh. Design* **35**(1/2):50–85 (2004), with a 2-y payback at today's gasoline price

**Midsize 5-seat Revolution SUV (2000)**

**Ultralight (1,889 lb) but ultrasafe**

**0-60 mph in 8.2 s (later 7.1)**

**66 mpg w/gasoline hybrid**

**114 mpg w/H<sub>2</sub> fuel cell**

**"We'll take two."**

*— Automobile  
magazine*

World  
Technology  
Award, 2003

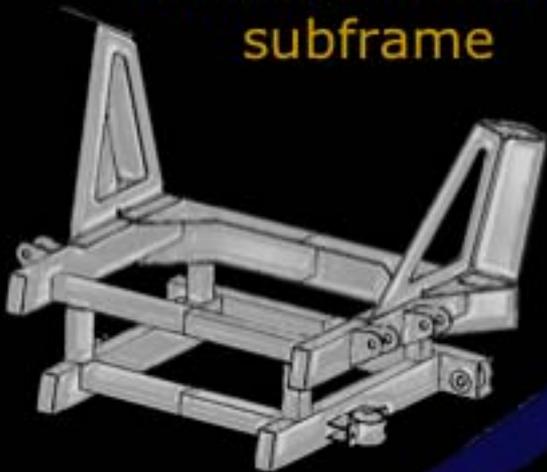

**Show car and a complete virtual design (2000),  
uncompromised, production-costed,  
manufacturable at competitive cost**

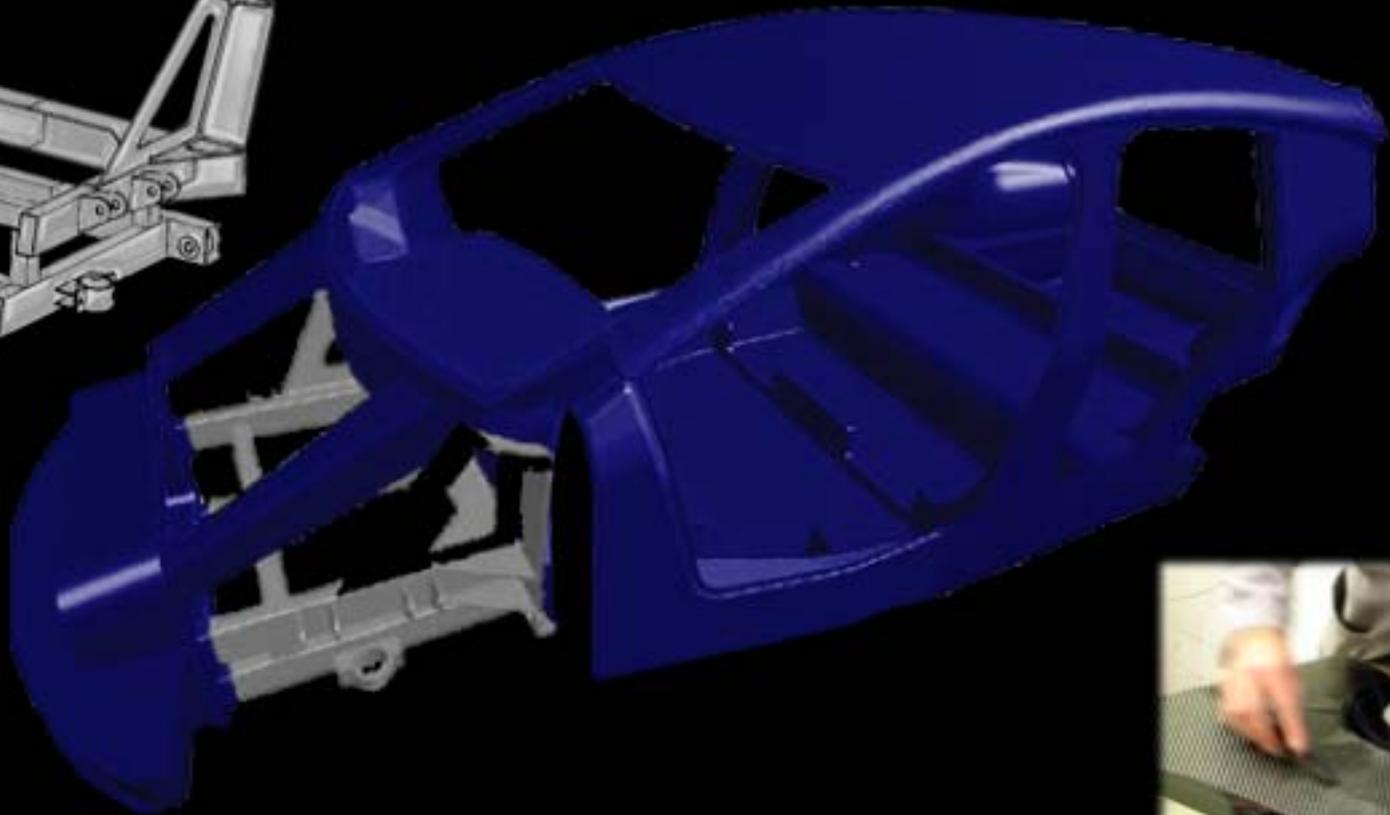

# Ultralight autobody materials

aluminum front  
subframe

advanced-composite  
passenger safety cell

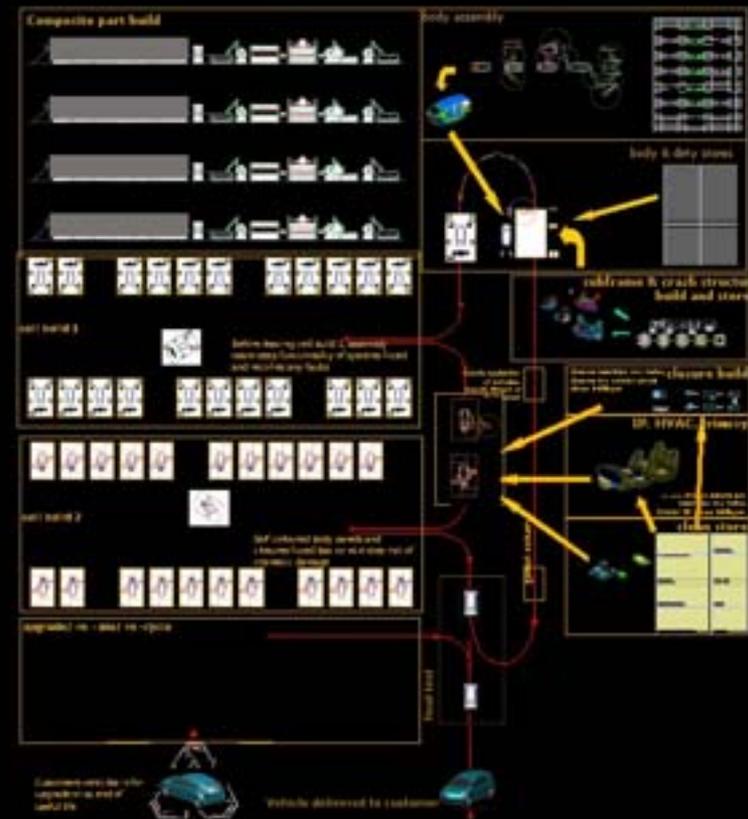

# Radically simplified manufacturing

## ◇ Mass customization

- *Revolution* designed for 50k/year production volume
- Integration, modular design, and low-cost assembly
- Low tooling and equipment cost

- 14 major structural parts, no hoists
- 14 low-pressure diesets (not  $\sim 10^3$ )
- Self-fixturing, detoleranced in 2 dim.
- No body shop, optional paint shop
- Plant gets 2/5 cheaper, 2/3 smaller

## Rapid progress with midvolume cost-competitive advanced composites

---

- ◇ BMW: 60 specialists at Landshut, world's biggest RTM press, series production ASAP
  - Already making >1k/y carbon roofs, hoods,...
  - Website strongly praises carbon composites
- ◇ Honda and Toyota: carbon airplanes
- ◇ Fiberforge™: small Colorado private firm
  - Patented digital automated fiber placement process
  - Thermoform to net shape, cycle times probably 1–2 min.
  - 80% of hand-layup aerospace performance, 20% of cost
  - Should beat Al in \$/part, and steel in \$/body up to ~40k/y
  - Mature process should beat steel in \$/car at any volume
  - JCI privately showed *Genus* chair at NAIAS Jan. 2005
  - Selling samples and small pilot runs to OEMs & suppliers

## Examples of recent Fiberforge parts

The Genus composite seat panel produced by Fiberforge. (Photos courtesy of Fiberforge.)

Genus features active seating surfaces that conform automatically to a person's body shape, breathable materials, and under-seat emergency lighting. (Photos courtesy of Johnson Controls Inc.)

JCI Genus 1.1-kg seat bucket and finished JCI concept seat, *Reinforced Plastics*, Feb. 2005, p. 40

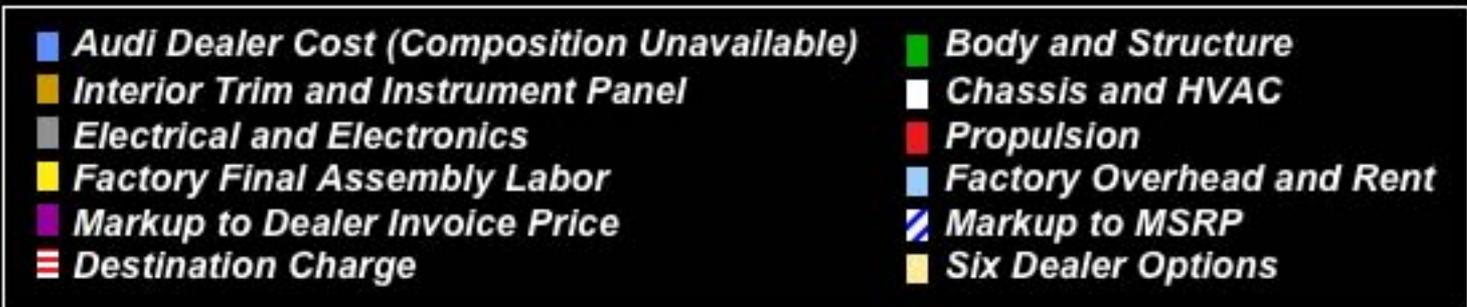

Anisotropic prototype part for a demanding non-automotive application, courtesy of Fiberforge

*Main advantages: breakthrough cost at midvolume, very low scrap, automated layup from CAD drawing*

# This means that ultralight hybrid midsize SUVs fueled with gasoline could achieve 67 mpg for 57¢/gal

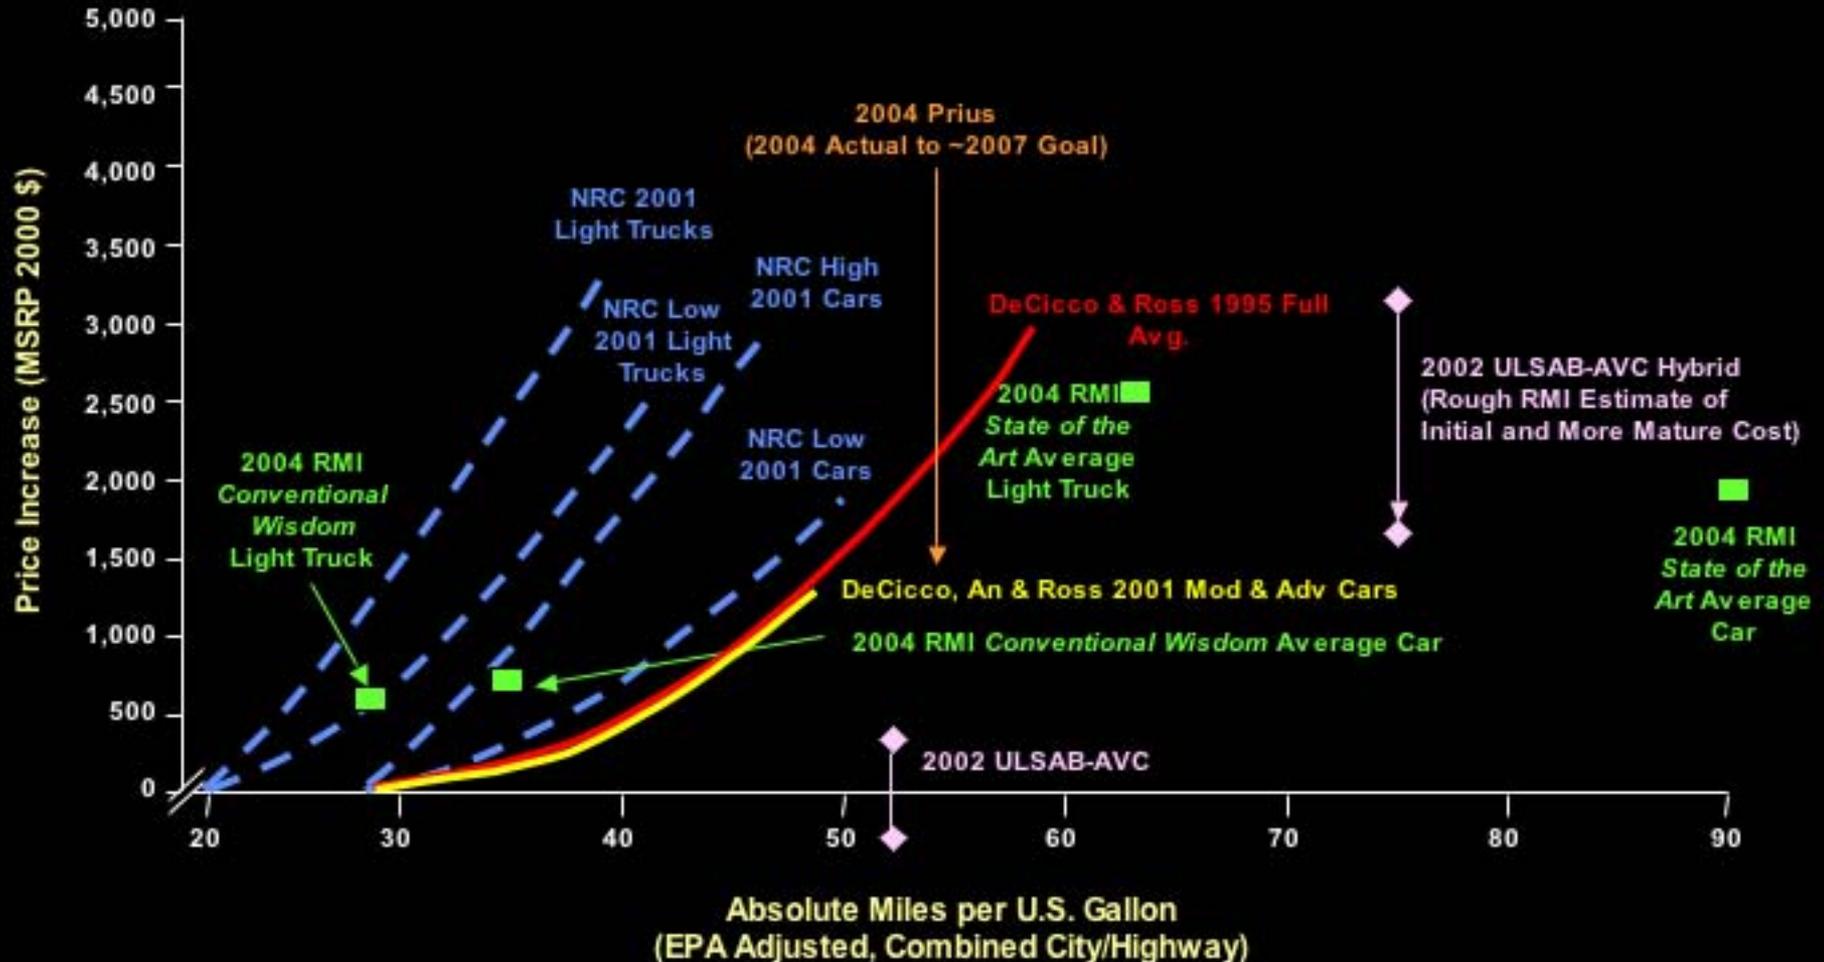

...based on a concept-SUV virtual design with two Tier Ones, production-costed mainly by bids (the rest by independent consultants and 9% by in-house models)

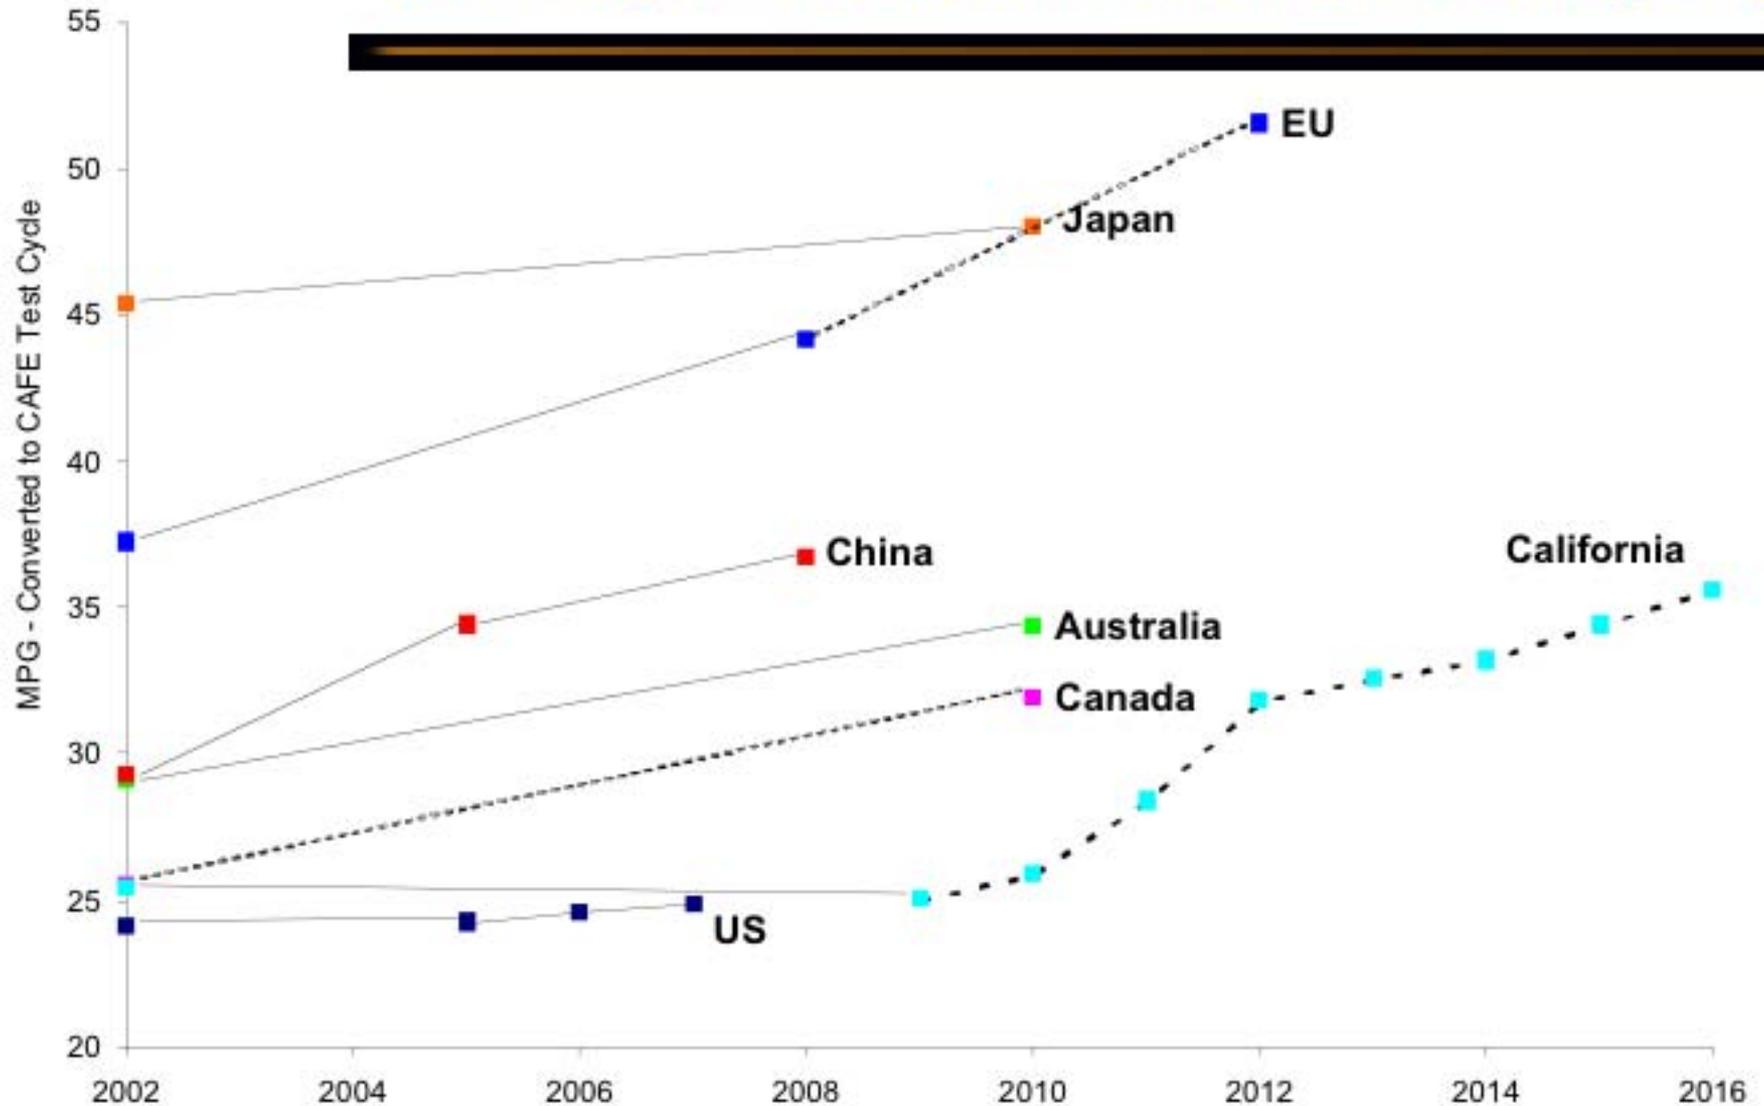

# Ultralight-but-safe light vehicles open a new, vast, roughly free ultralight-hybrid design space

All Vehicles Shown in Green are Adjusted to EIA's 2025 Acceleration Capability for That Class of Vehicle  
RMI's 2004 Average Vehicles are for EIA's 2025 Sales Mix

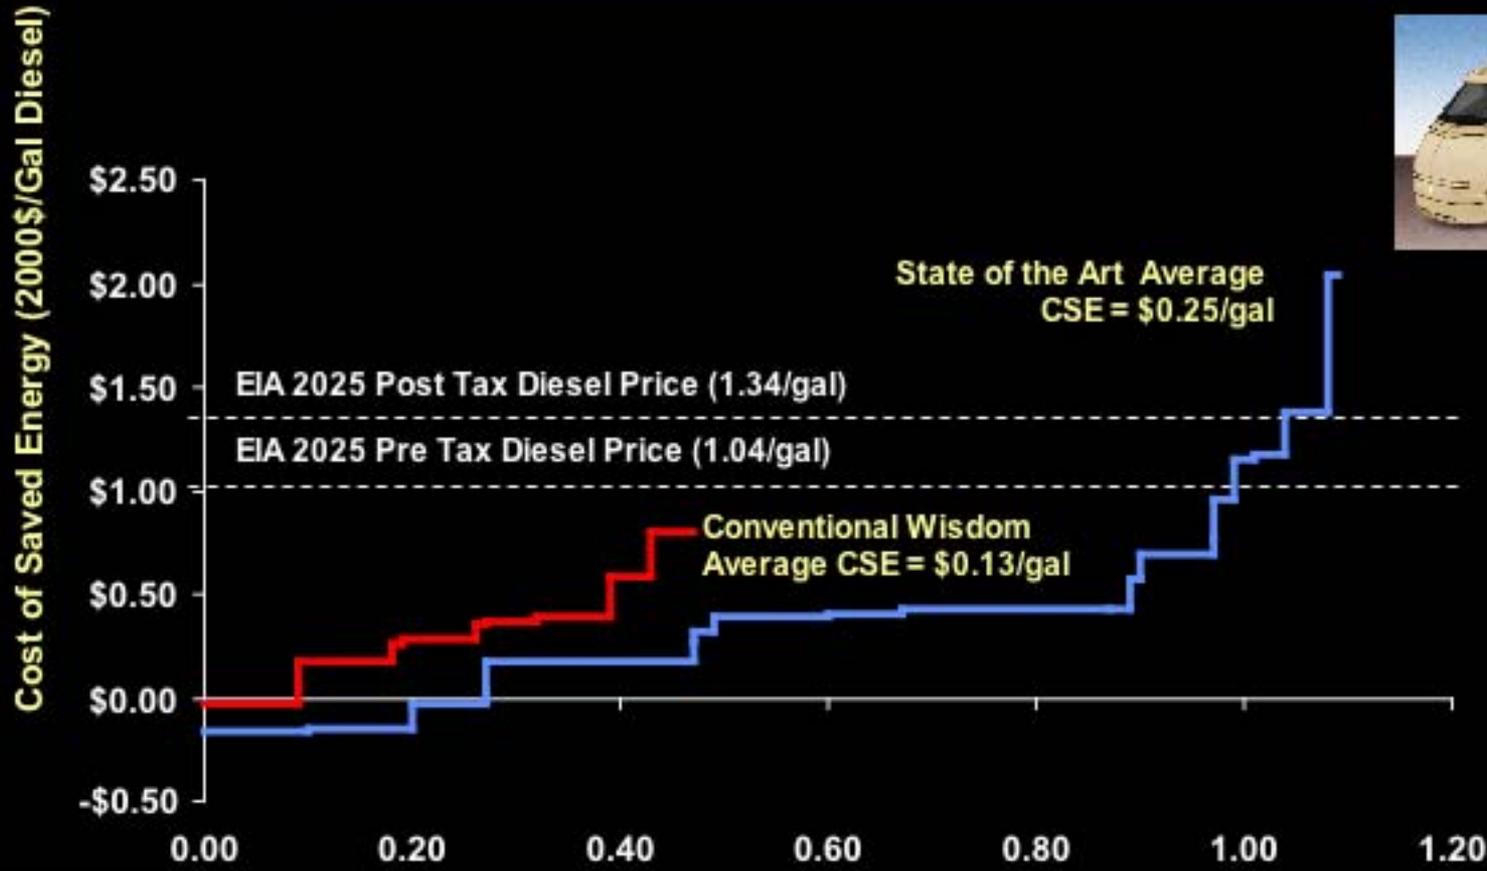

# Current and projected new-car eff. stds. (in US CAFE miles-NEDC/gal.)

Source: F. An & A. Sauer, "Comparison of Passenger Vehicle Fuel Economy and GHG Emission Standards Around the World," Pew Center on Global Climate Change, Dec.

# Heavy trucks use 12% of all U.S. oil in 2025; the same technologies could save 65% of that use at 25¢/gal diesel

**End: 11.8 mpg, then ~16-equivalent w/further improvements**

**Diesel Fuel Saved (Mbbbl/d) in 2025 (vs. EIA Jan. 2004 Reference Case)**

**Start: 6.2 mpg**

Main sources: MIT, ANL, industry tests

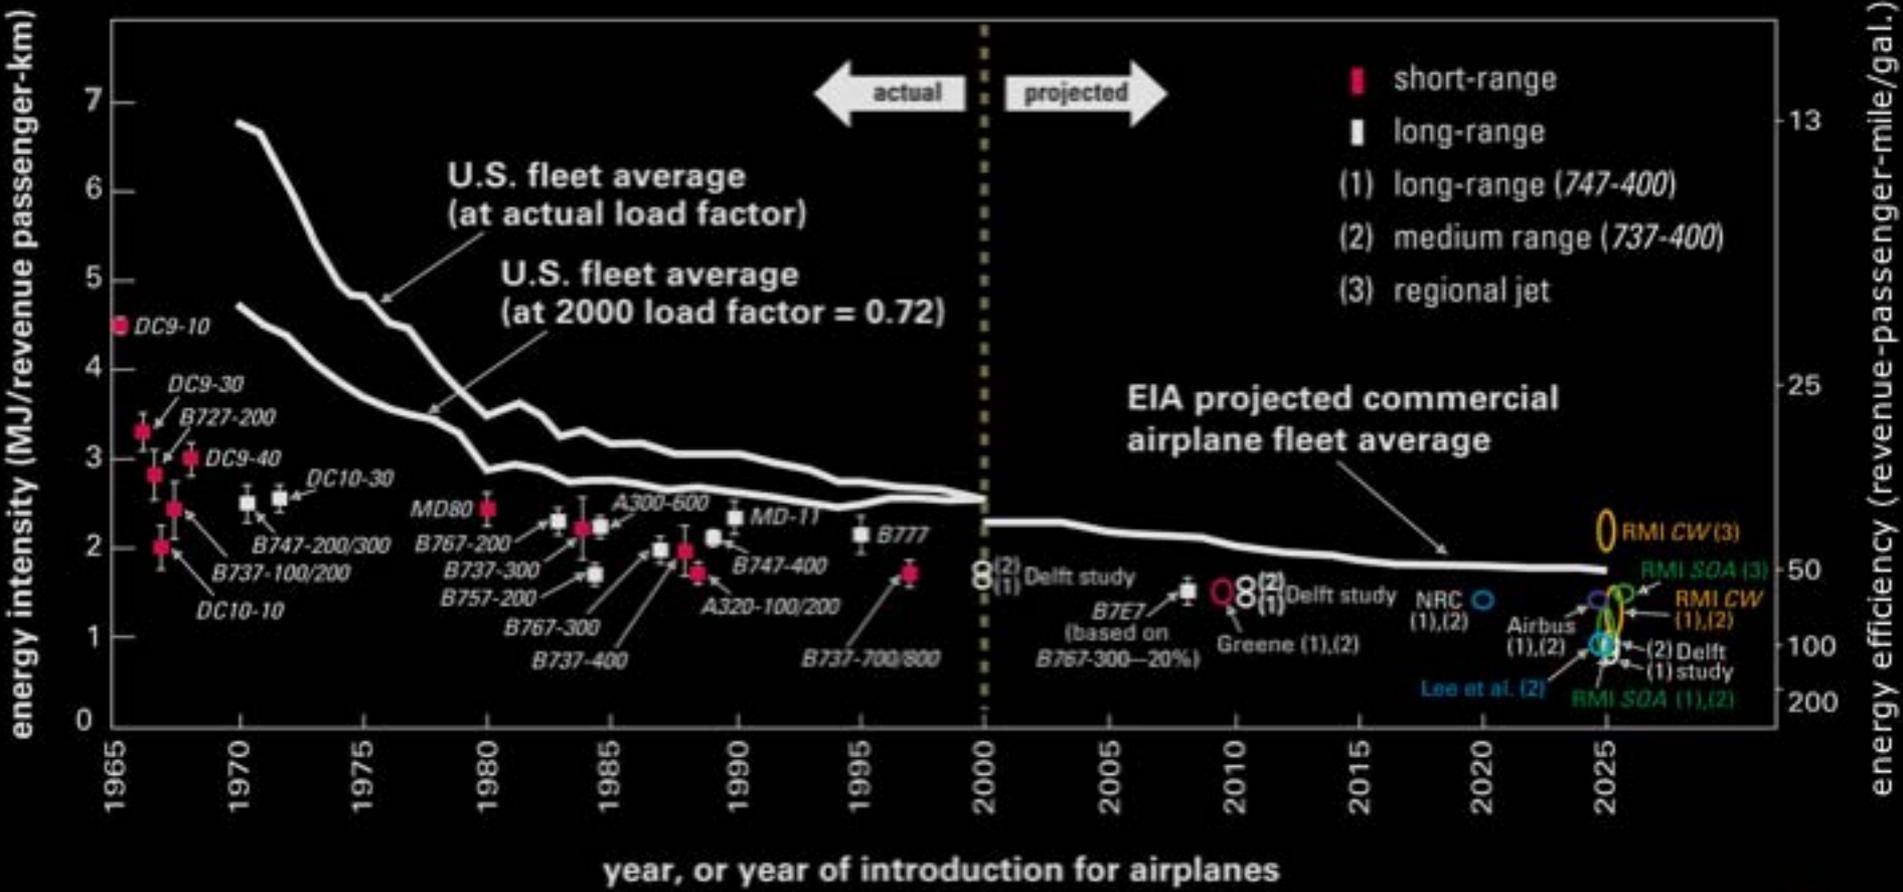

# Airplanes: industry agrees fleet can get 2–3× more efficient

NASA image of Blended-Wing-Body

Boeing 787 Interior

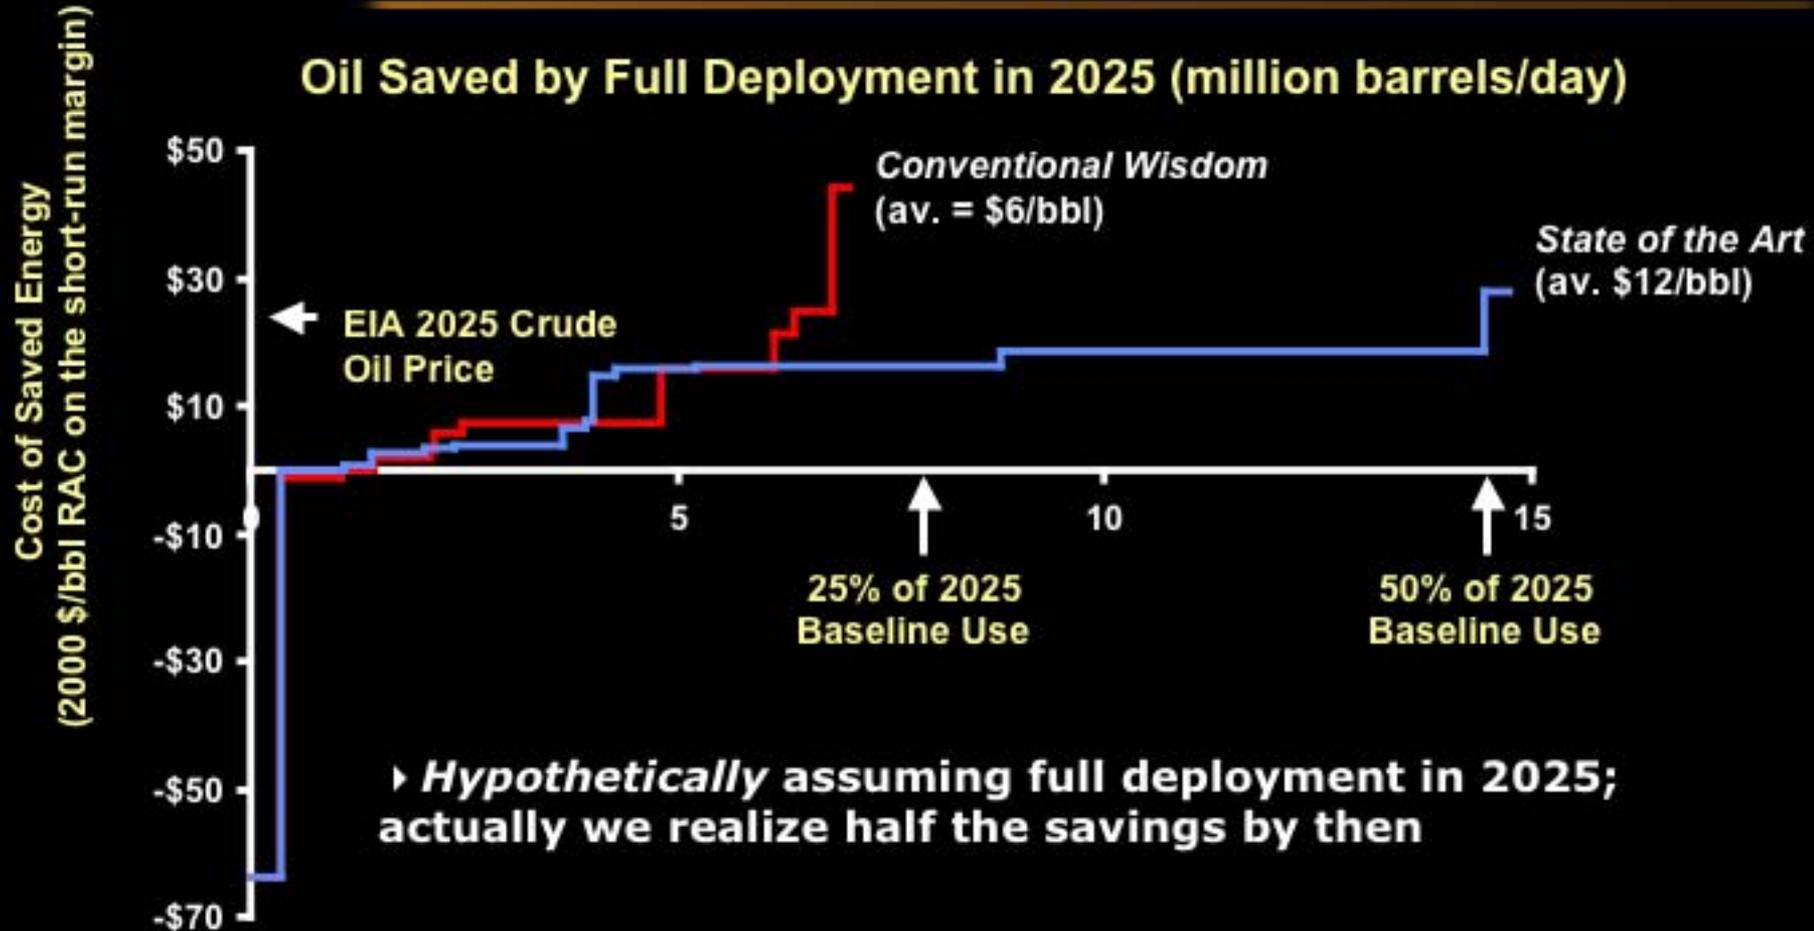

- ▶ Keys: advanced composites, new engines, aerodynamics
- ▶ Could save 45% of EIA 2025 fuel @ av. 46¢/gal Jet-A

**It pays to be bold: saving half the oil for \$12/bbl is better than saving a fourth at \$6/bbl – else alt. supplies cost too much**

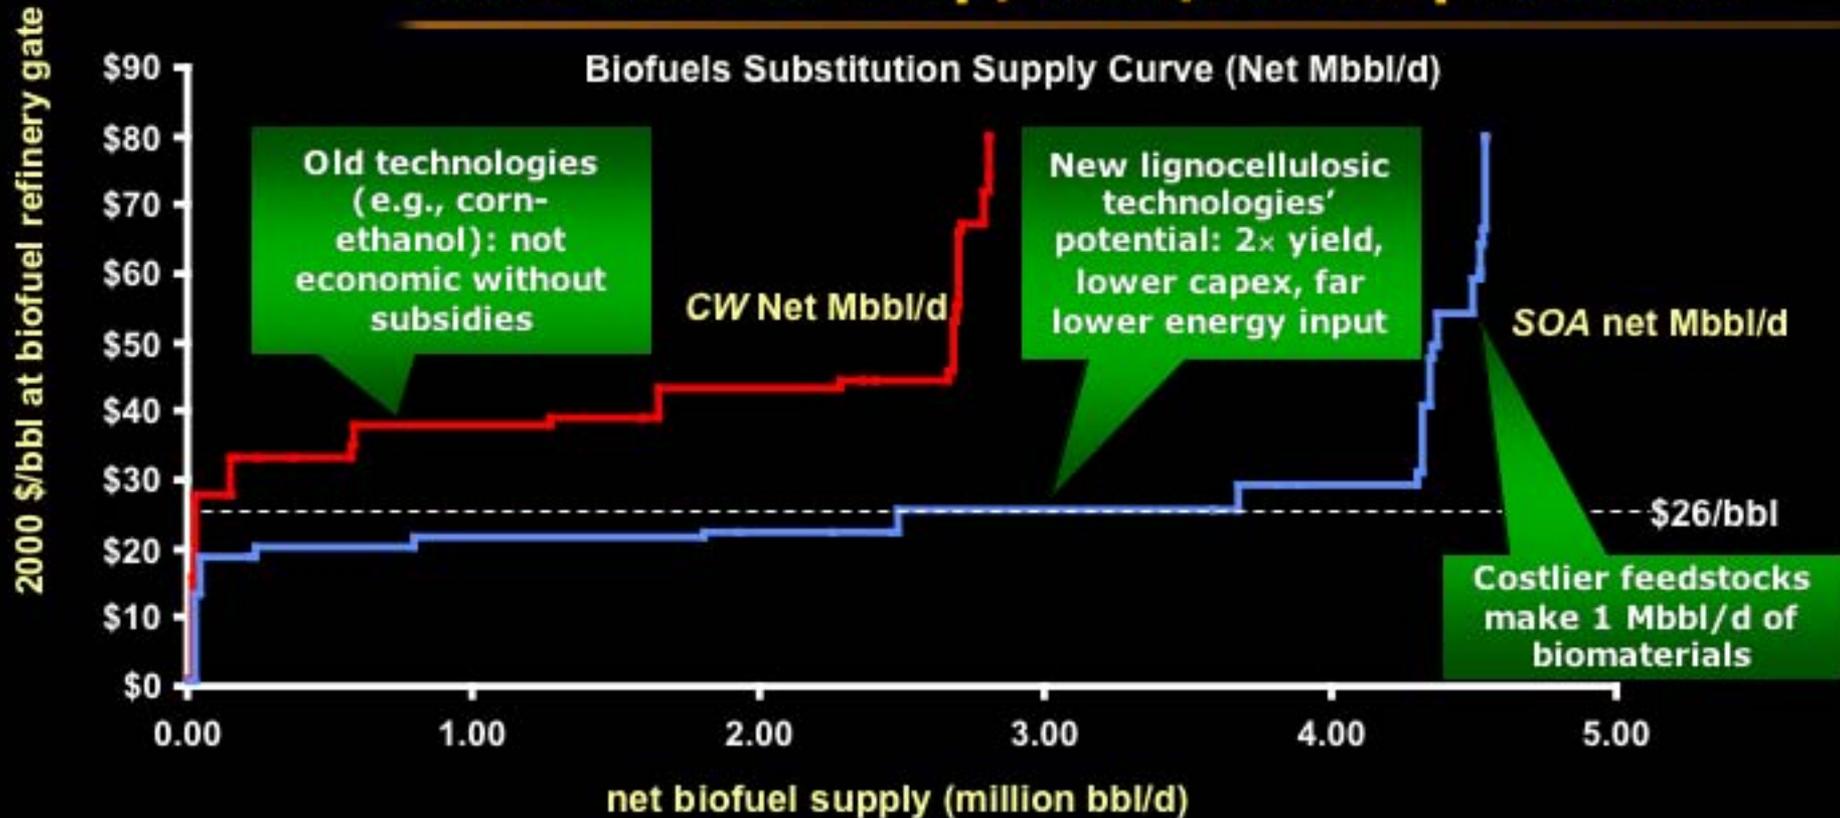

**Oil Saved by Full Deployment in 2025 (million barrels/day)**

**No further invention is assumed during 2005–2025**

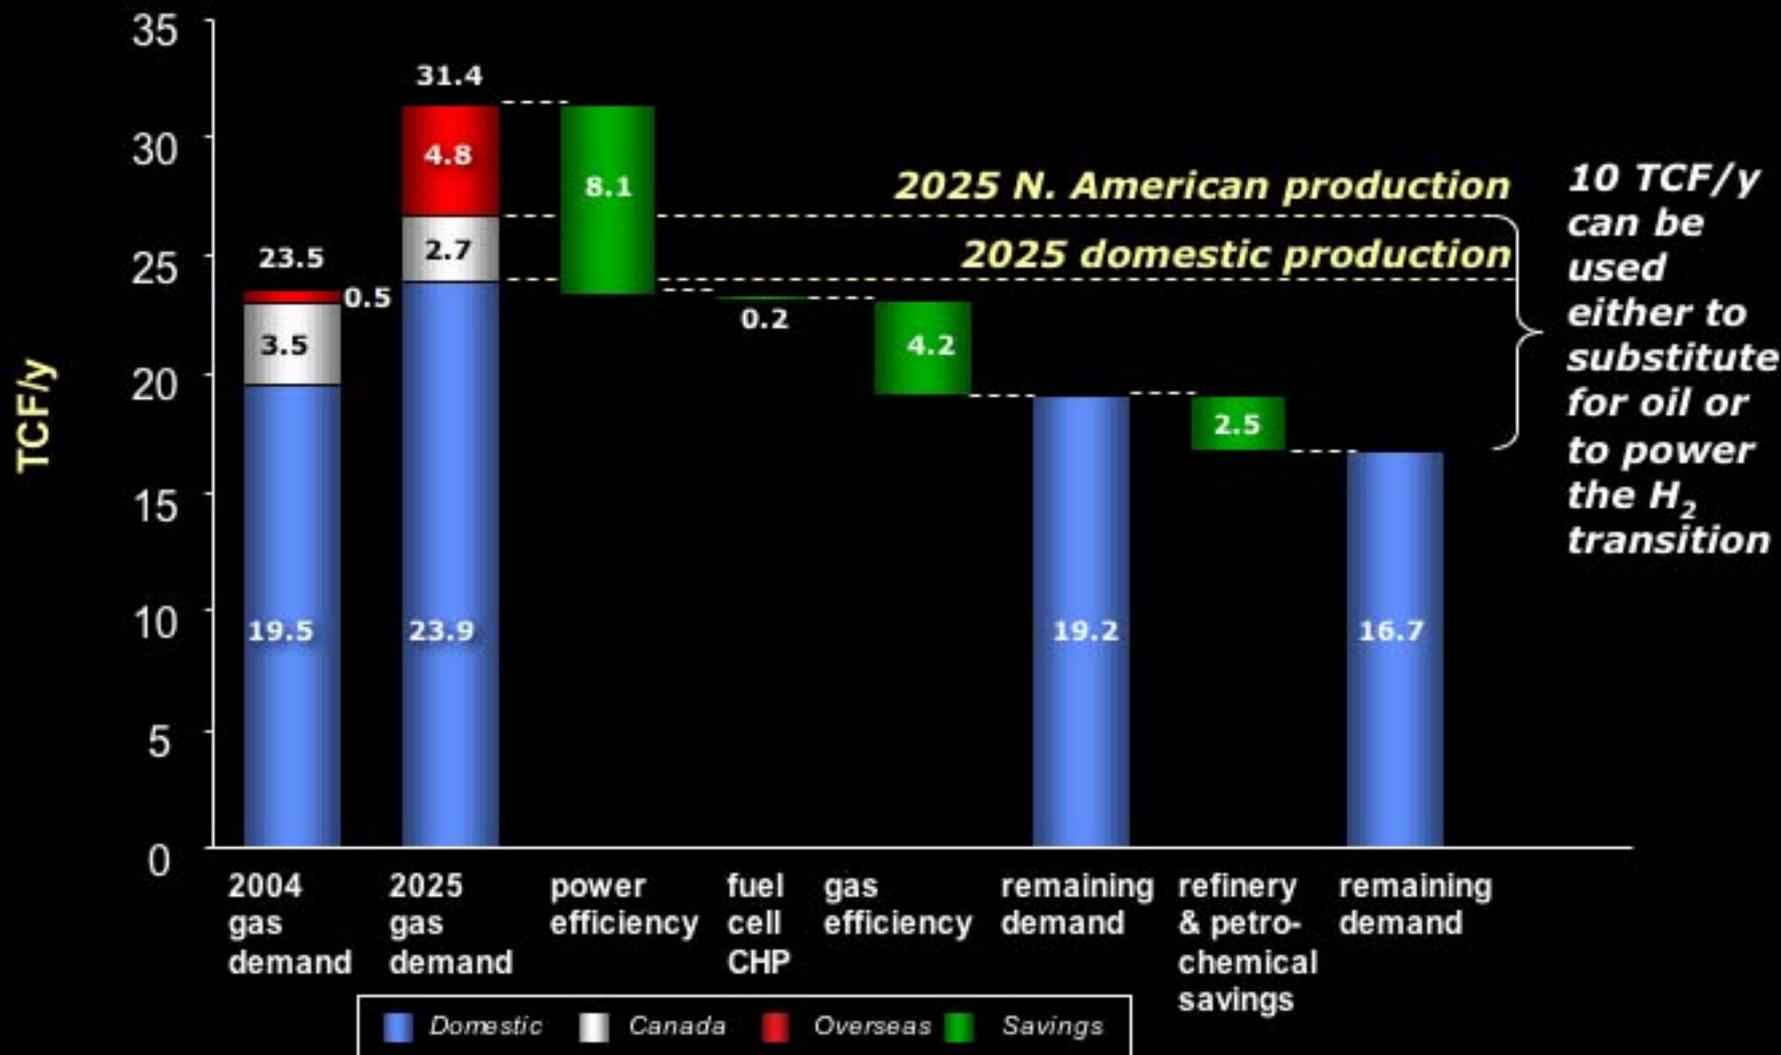

# New biofuel technologies could provide 3.7 Mbbl/d cheaper than oil—without subsidies or crop/land/water problems

- Brazil has replaced 1/4 of its gasoline with sugar-cane ethanol, competitive without subsidy; oil savings so far are 50x the startup subsidy; exporting 2007–08 to Japan and China
- Europe in 2003 made 17x as much biodiesel as U.S.: oil companies distribute it; shifts farmers from subsidy to revenue

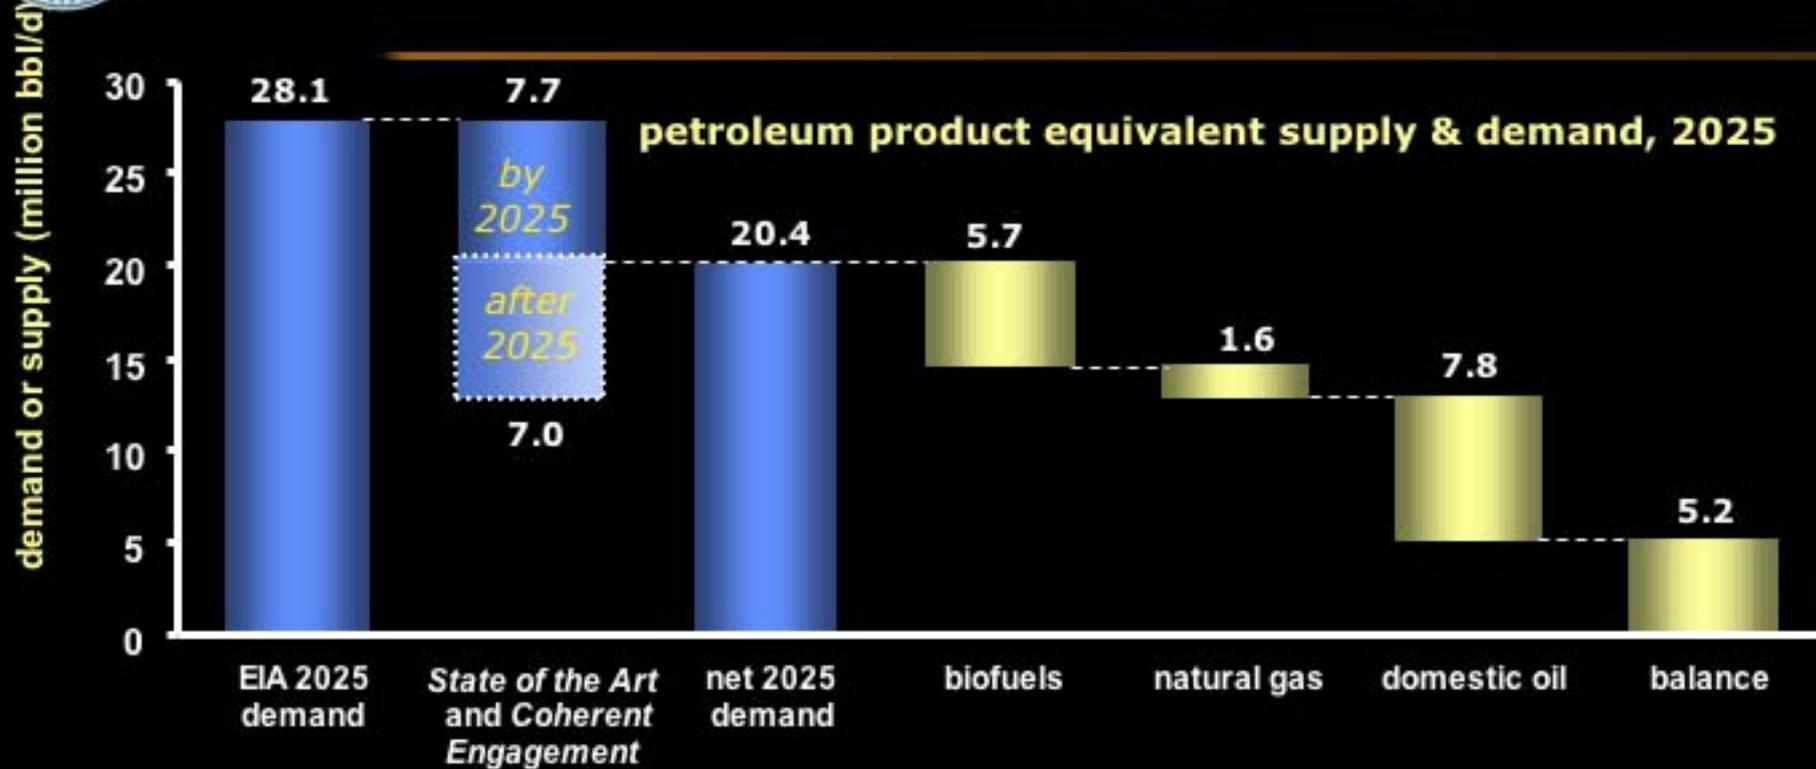

# Over 12 TCF/y of natural gas could be saved by lucrative energy efficiency

# 2025 demand-supply integration

## Great flexibility of ways and timing to *eliminate* oil in next few decades

- Buy more efficiency (it's costing only half as much as the oil it replaces)
- Efficiency is only half captured by 2025—7 Mbbl/d still in process
- "Balance" can import crude oil/product (can be all N. Amer.) or biofuels
- Or saved U.S. natural gas @ \$0.9/MBTU can fill the "balance"...or
- H<sub>2</sub> from saved U.S. natural gas can displace "balance" *plus* domestic oil
- Not counting other options, e.g., Dakotas windpower—huge H<sub>2</sub> resource

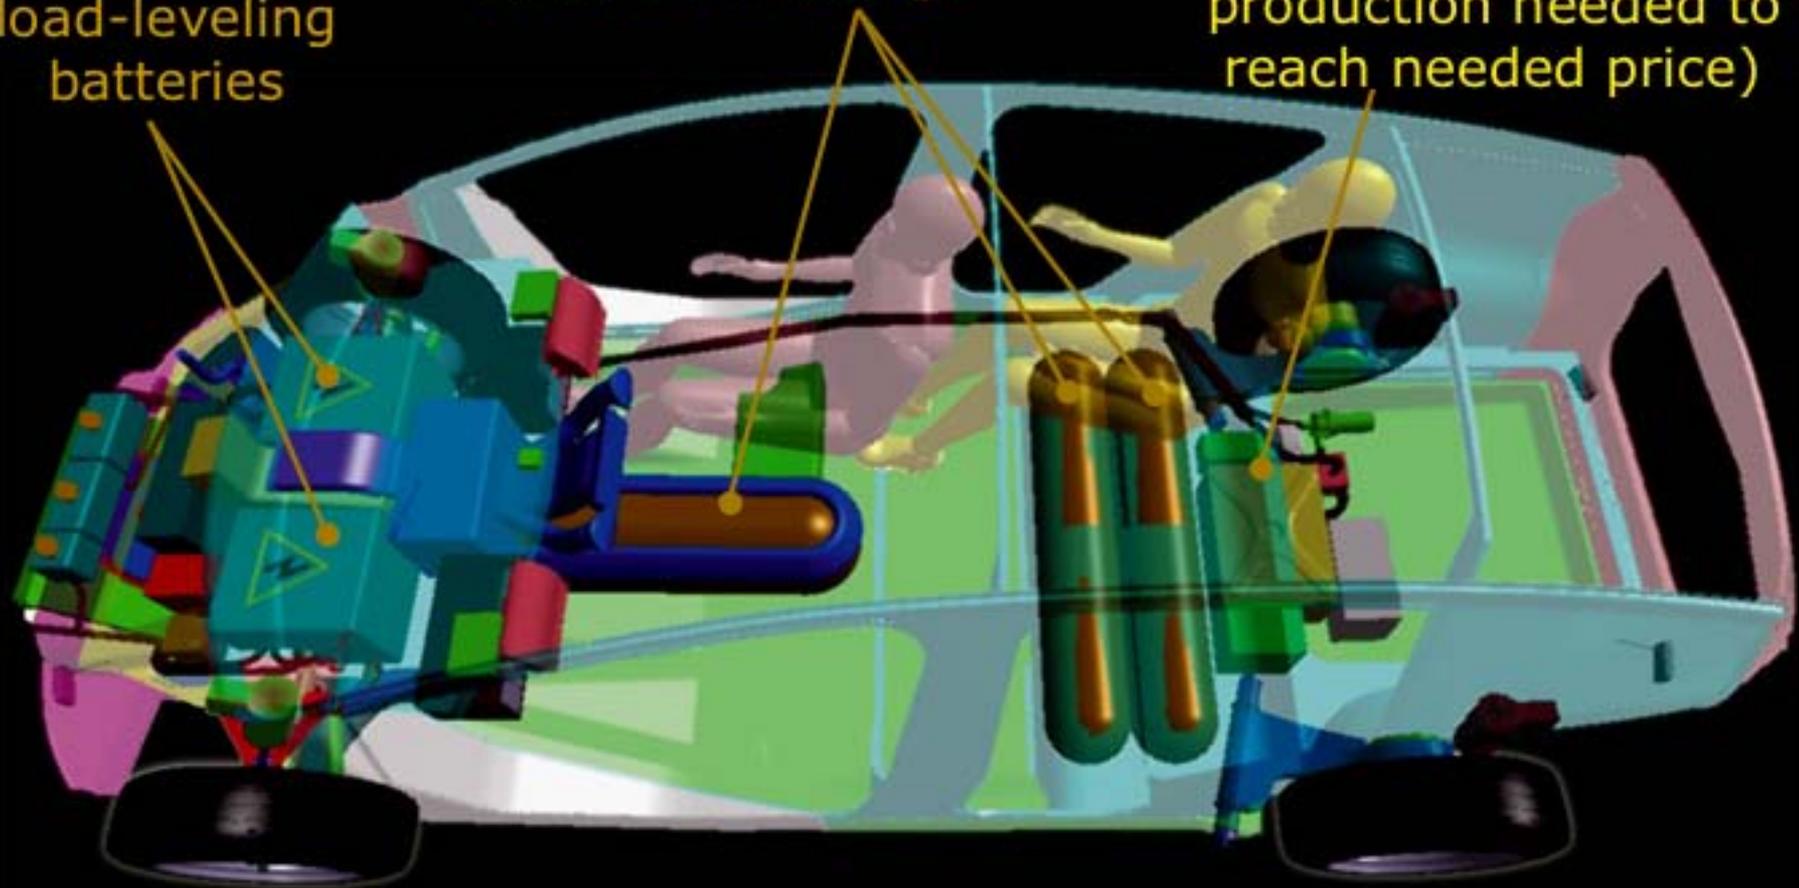

**1,889-lb curb mass (+2), low drag, load +3, so 55 mph on same power as normal a/c, so ready now for direct hydrogen fuel cells**

137-liter 345-bar H<sub>2</sub> storage (small enough to package) for 330-mile range

35-kW fuel cell (small enough to afford early: ~32x less cumulative production needed to reach needed price)

35-kW load-leveling batteries

# So the first automakers to go ultralight wins the fuel-cell race

Vehicle	Power (kW)	Type	Cost @ \$100/kW	Range (km)
<i>Hypercara Revolution</i>	35	hybrid	\$3,500	531
<i>Jeep Commander 2</i>	50	hybrid	\$ 5,000	190
<i>Hyundai Santa Fe FCV</i>	75	fuel cell	\$ 7,500	402
<i>Honda FCX-V4</i>	85	fuel cell	\$ 8,500	298
<i>Ford Focus FCV</i>	85	hybrid	\$ 8,500	322
<i>Toyota FCHV-4</i>	90	hybrid	\$ 9,000	249
<i>GM HydroGen III</i>	94	fuel cell	\$ 9,400	402
<i>GM Hy-Wire</i>	94	fuel cell	\$ 9,400	129

# The creative-destruction challenge for oil companies

- ▶ The Oil Endgame is starting: the chairs of 4 oil majors and 3 car majors have said so
- ▶ Oil will probably become uncompetitive even at low prices before it becomes unavailable even at high prices
- ▶ Biofuels can be the transitional product line, as oil companies are exploiting in Europe
- ▶ Compelling arguments for changing business model to provide mobility and access, not gallons
- ▶ In the future,  $H_2$  in hydrocarbons will be worth more without C than with C (even if nobody pays to protect the climate), so it's better to take  $H_2$  out of HCs (reform) than to put more in (refine); oil asset values may be sustained or increased

# What if DoD investment in advanced light materials could transform the U.S. economy as profoundly as Internet, GPS, and chips ?

## The prize

- ◆ Advanced materials & propulsion systems can find a Saudi Arabia (>9 Mbbl/d) of saved oil under Detroit & Seattle...
- ◆ ...and help DoD transform its forces, strengthen warfighting capability, and cut fuel cost by billions of \$/y and logistics cost by tens of billions of \$/y
- ◆ The U.S. could cut oil use by 50% by 2025, imports by 75%
- ◆ The key DoD action needed is S&T investment in advanced materials, especially high-volume/low-cost manufacturing

- ◆ A nega-Gulf every 7 y
- ◆ Vastly less world dependence on oil and conflict over oil
- ◆ A competitive Big 3
- ◆ Cheaper oil; more balanced U.S. trade, global development, and diplomacy
- ◆ More capable and confident warfighting
- ◆ Less need for it
- ◆ A safer world

## Four basic market failures

---

- ◇ Oil is priced below its societal cost
- ◇ Most customers are very short-sighted
- ◇ Most customers have poor information
- ◇ Most managers resist disruptive innovations

Policy portfolio must turn these obstacles into business opportunities and accelerate adoption of advanced-technology vehicles

# Five ways government can help

---

- 1) Stimulate demand for very efficient vehicles**
  - **Feebates—revenue- and size-neutral, more automaker profit**
  - **Create a new million-car-a-year market through leasing to low-income customers (and scrapping clunkers)**
  - **Smart military and government fleet procurement; “Golden Carrot” and “Platinum Carrot” to speed innovation**
  - **Heavy-truck-buyer info/leadership, airline loan guarantees**
- 2) Build vibrant 21<sup>st</sup> Century industries by sharing R&D risk and deploying faster than the private market**
  - **Military S&T should finance advanced materials development**
- 3) Lower risk of investment for new manufacturing plants through loan guarantees to automakers**
- 4) Support development of domestic energy supply infrastructure (hydrocarbons → carbohydrates)**
- 5) Remove barriers to efficiency through coherent policies and purging perverse incentives**

# State policy opportunities (once you've DONE utility decoupling!)

---

## ◇ Light vehicles

- Revenue- and size-neutral feebates; shift registration/excise?
- Smart procurement (aggregating state and local?)
- Pay-at-the-pump insurance; shift tax from fuels to roads/driving
- Fund initial dealer carrying charges/bonuses for superefficient cars

## ◇ Heavy trucks

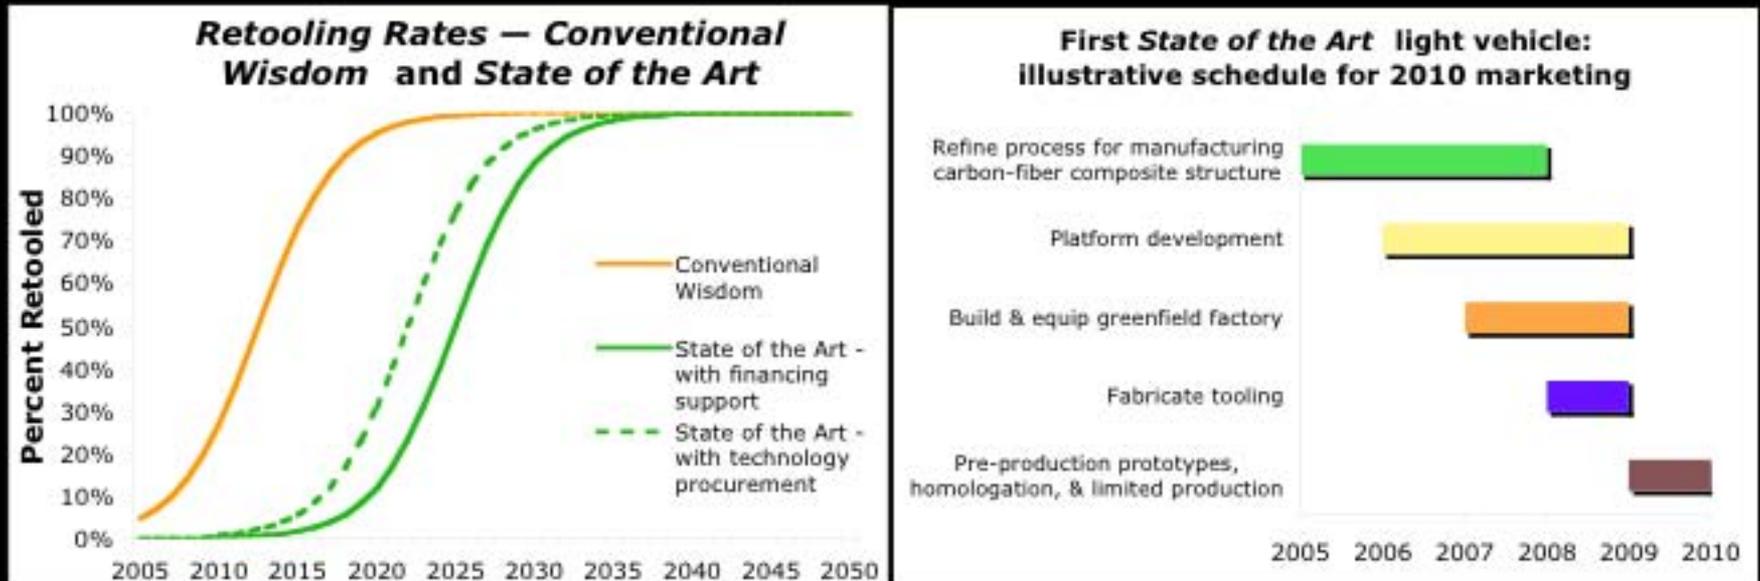

- Allow extra axle, 2-/3-trailer combos w/better brakes, 60 mph
- Raise GVWR to EU norm (110klb), 14'H, 59'L
- Require fuel-economy driver's ed
- Encourage truckmakers to get first-mover advantage—*e.g.* Oregon Business Energy Tax Credit (up to 35% of \$10M/project), loans,...

## ◇ Biofuels (good fit to ag & water needs & capabilities)

- Procurement, labeling, detaxation?, ?bonds, totalflex vehicles

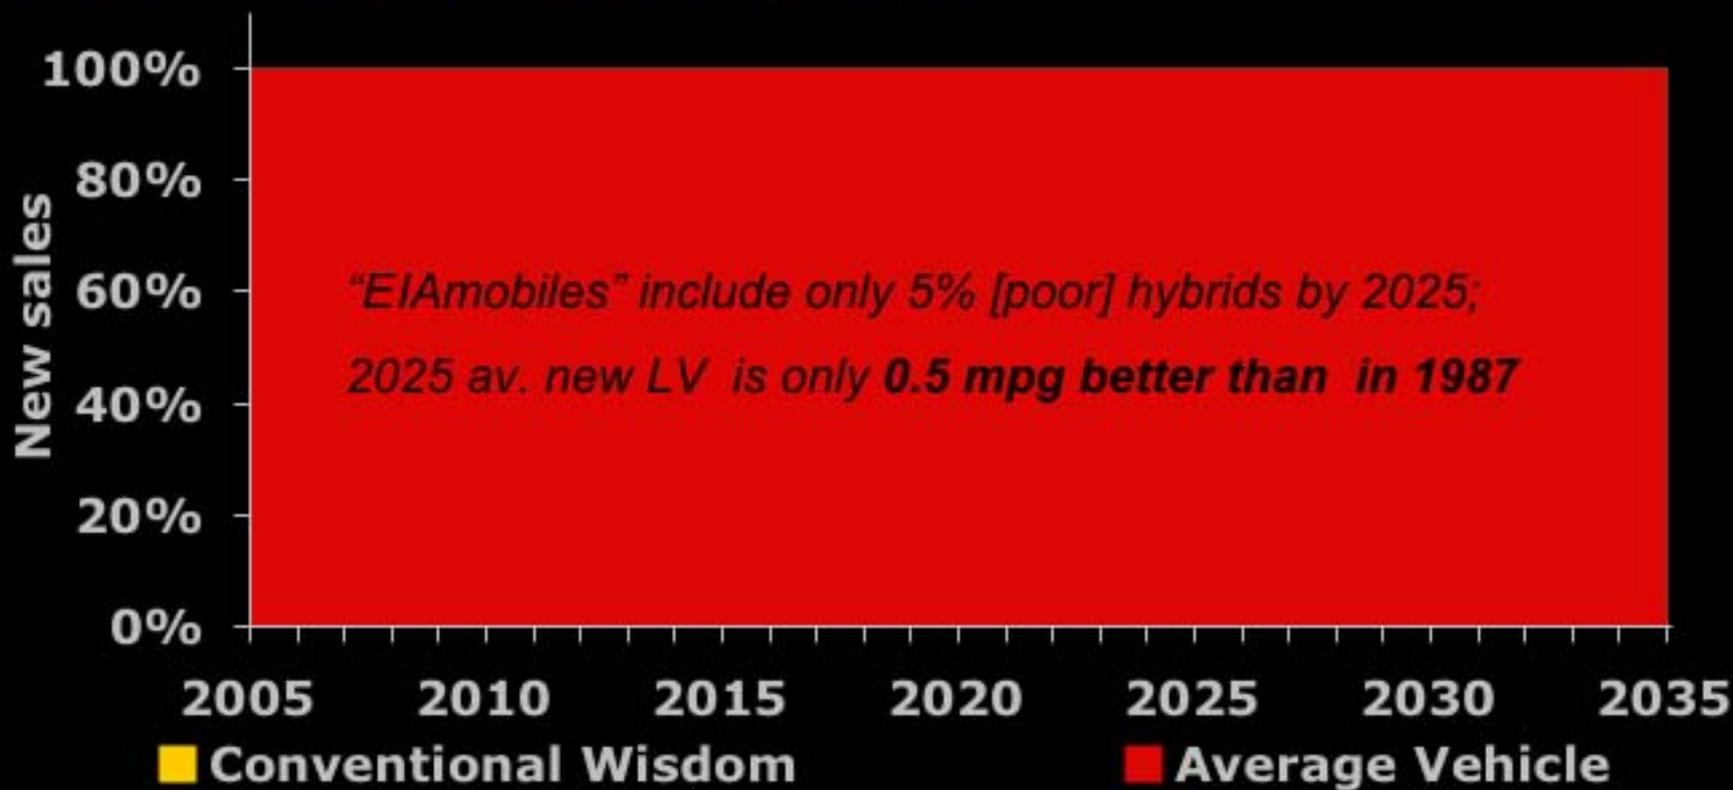

# Bringing affordable, ultralight, advanced-composite vehicles to market starting 2010

- Insider view of industry programs and state of mfg. process development supports this timeline
- Some OEMs may be faster: BMW 2005?; Honda & Toyota entering the carbon-fiber aircraft business

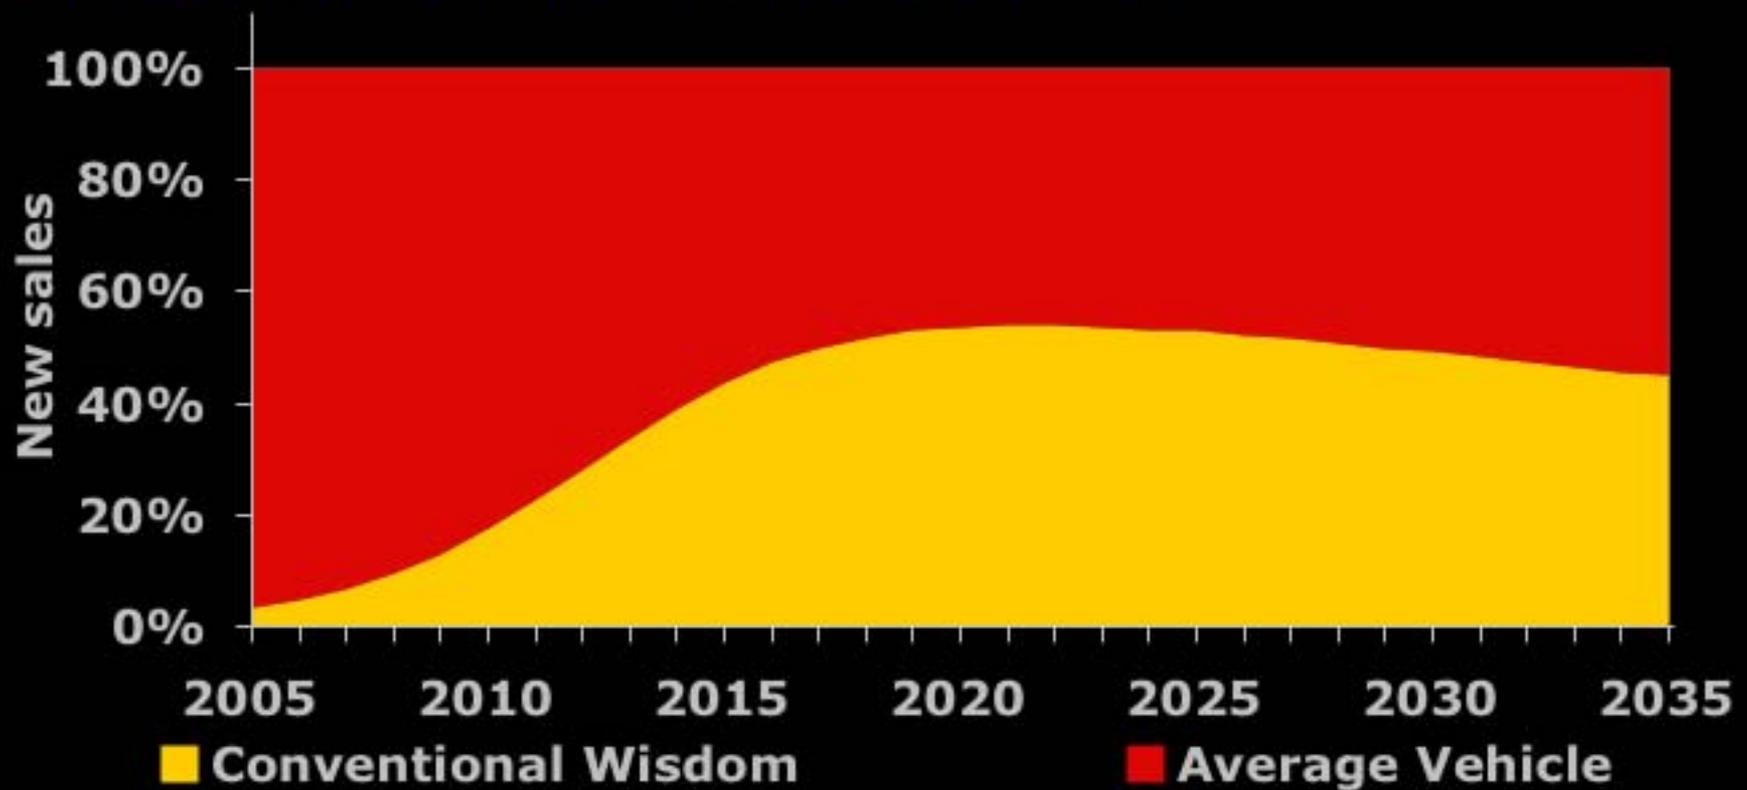

# U.S. Energy Information Administration (EIA) scenario

Absent demand-driving policies and *Conventional Wisdom* and *State of the Art* technologies

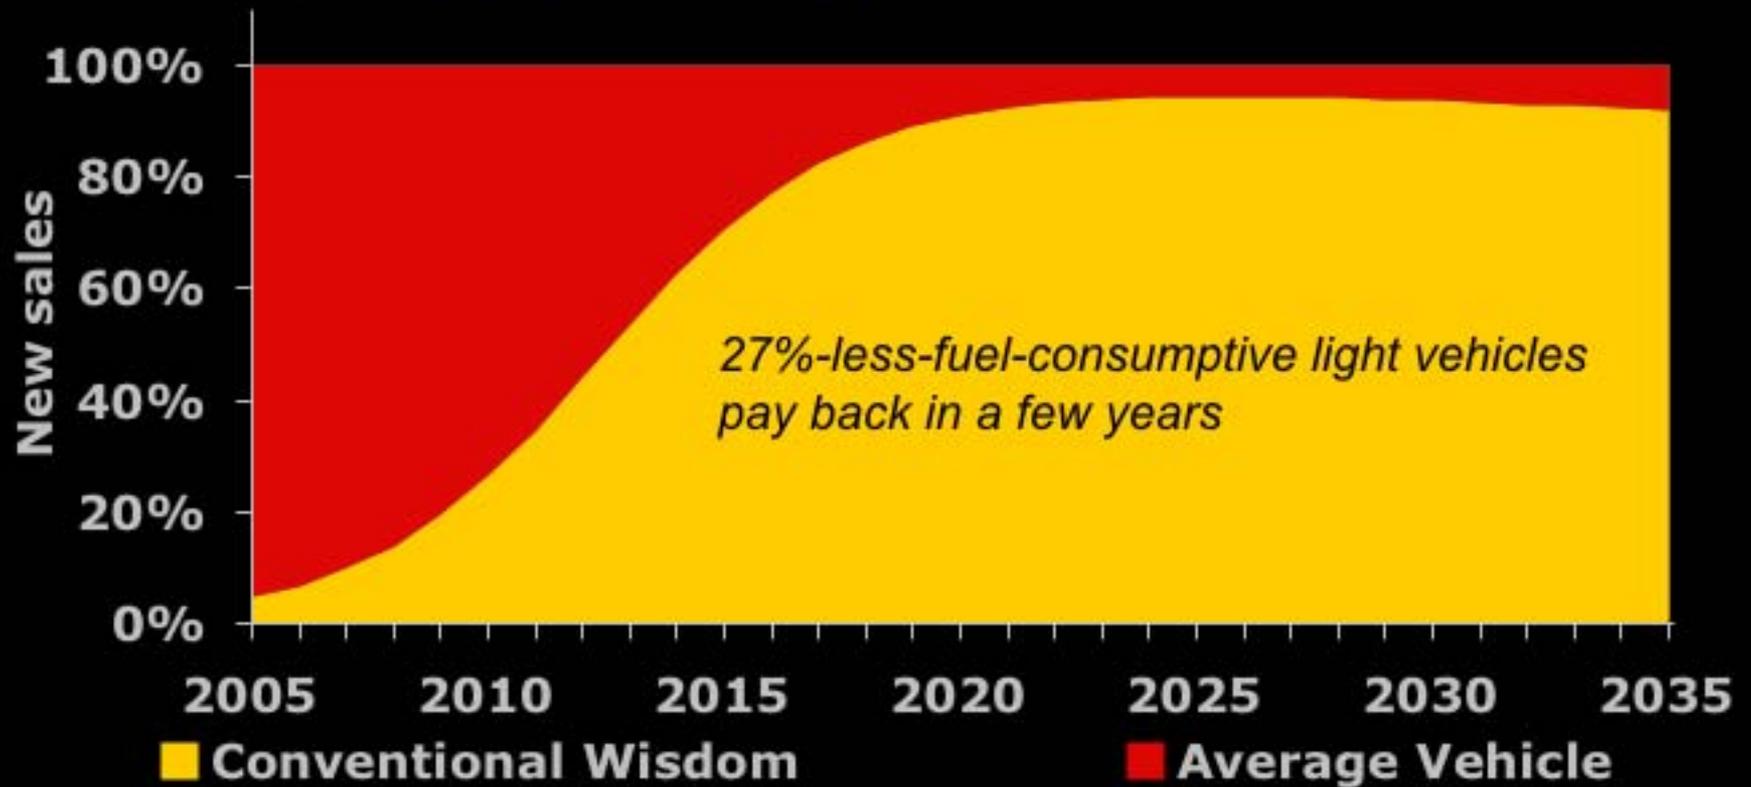

# Drift scenario

**Absent demand-driving policies, *Conventional Wisdom* vehicles capture half the market in 2020**

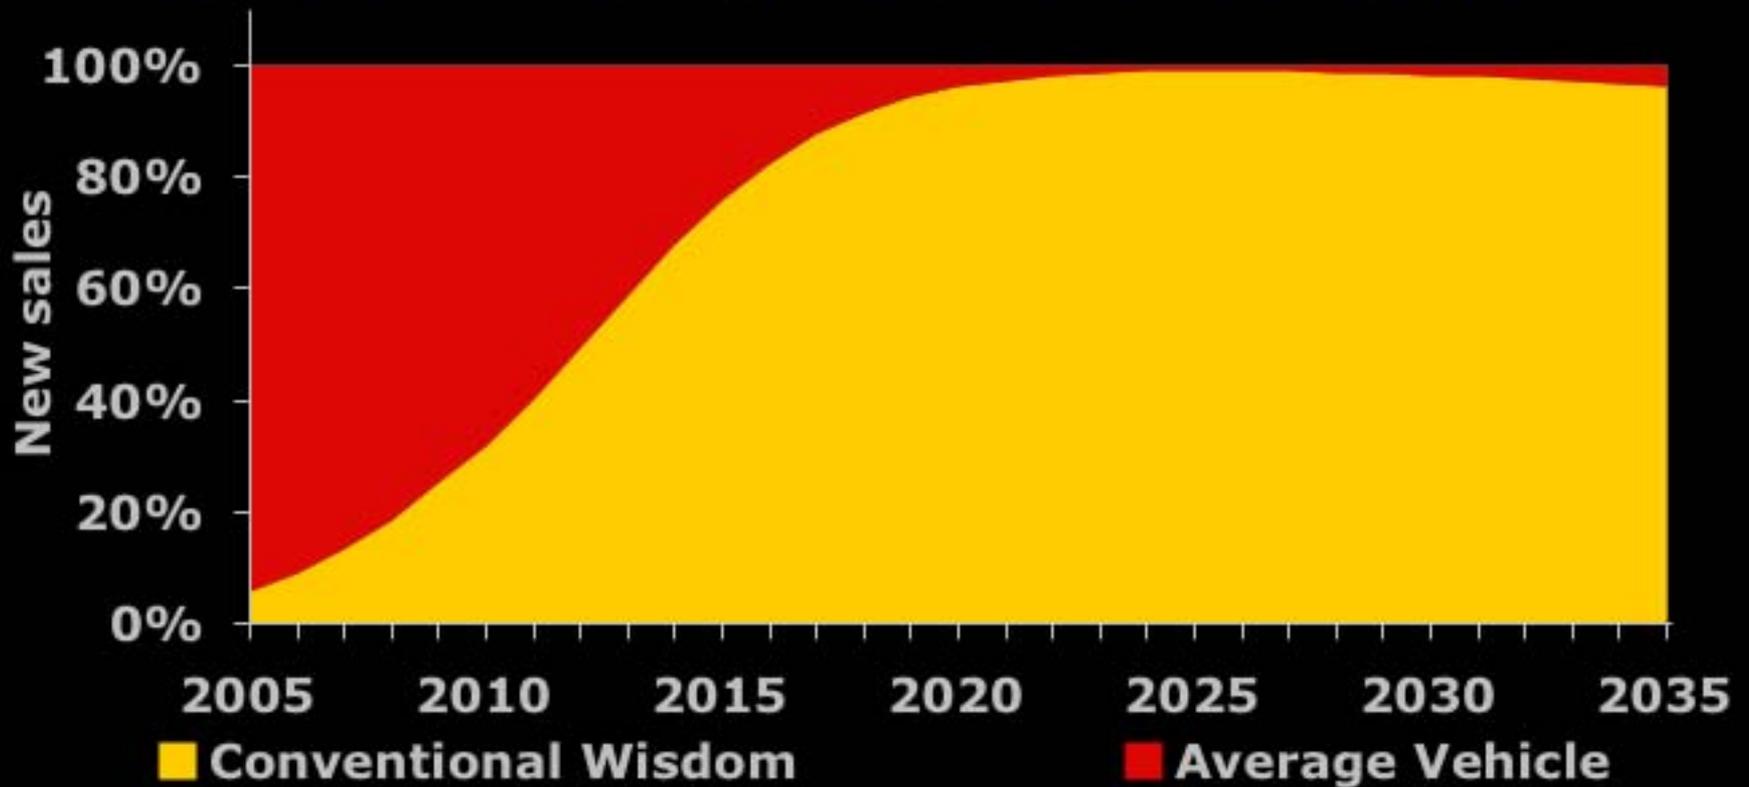

# Let's Get Started scenario

Feebates at the \$1,000/0.01 gpm rate allow buyers to see 14, not 3, years of fuel savings

# Let's Get Started scenario

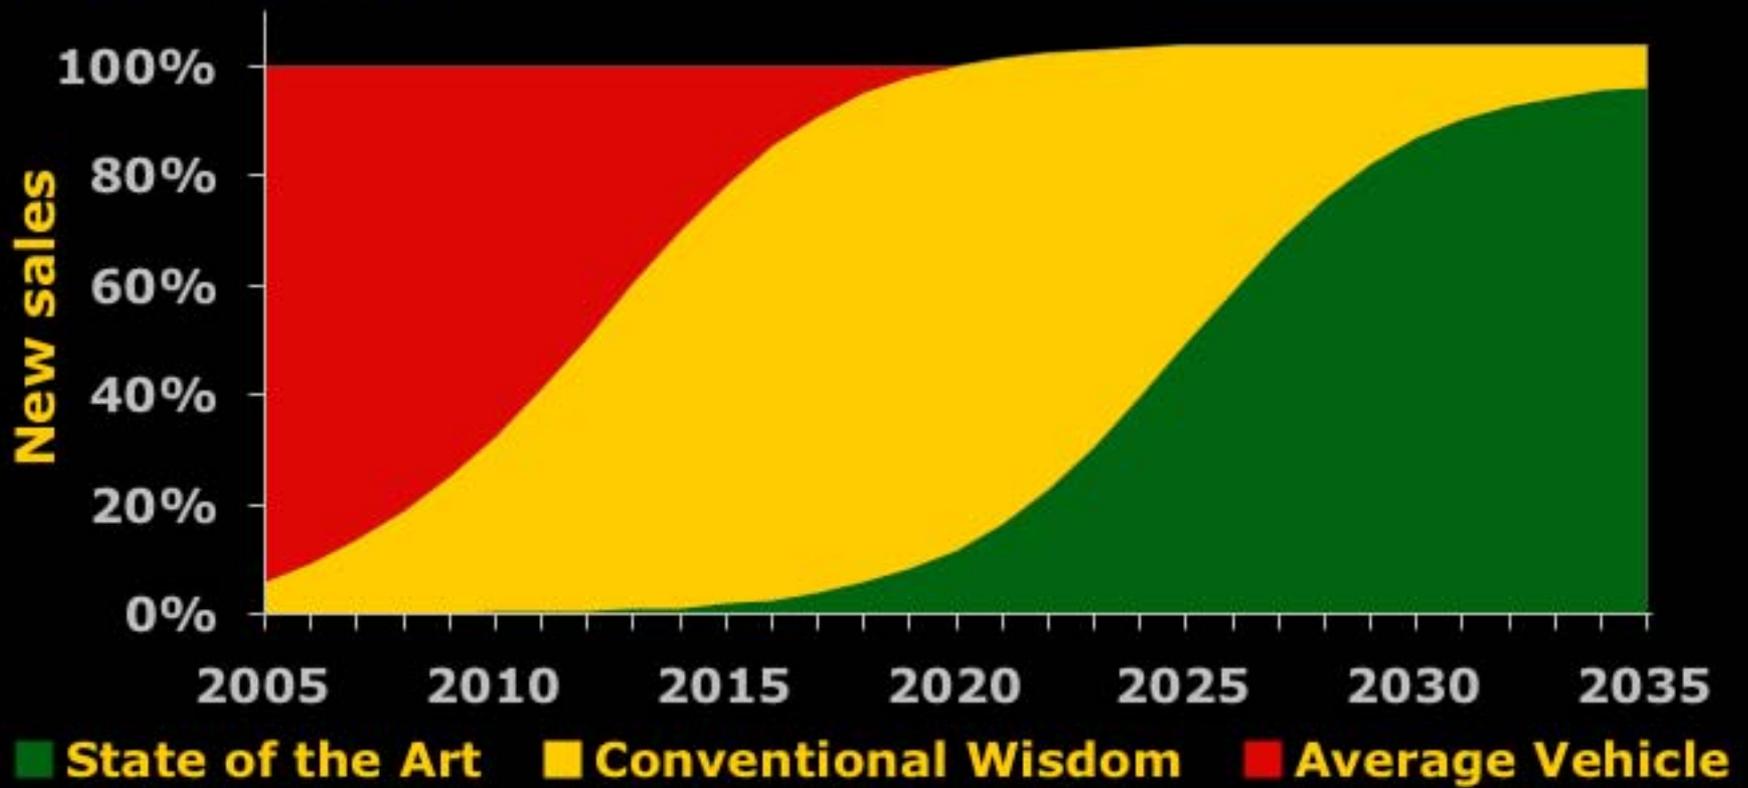

Low-income scrap-and-replace program is not a big oil saver, but it's vital for equitable social development

Reality check: a 2025 fleet as efficient as 2004 hybrid cars & SUVs would save 1/6 of all 2025 oil use (2 Gulfs' worth), costing ~\$45b/y

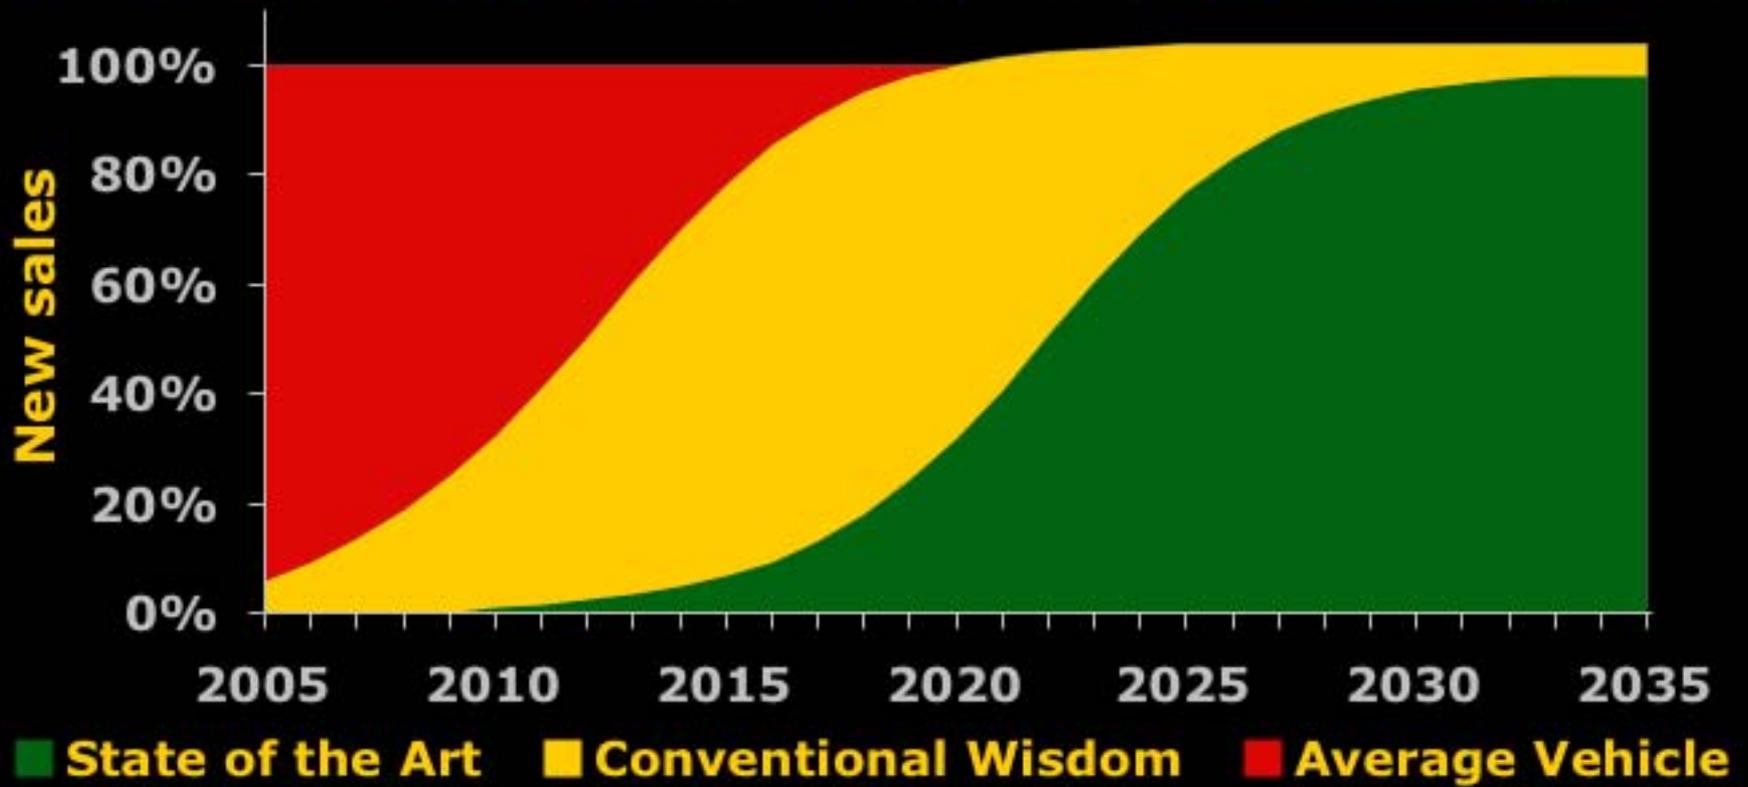

# Mobilization: Accelerating Change

Increasing the feebate rate to \$2,000/0.01 gpm starts to count public goods

# Mobilization: Accelerating Change

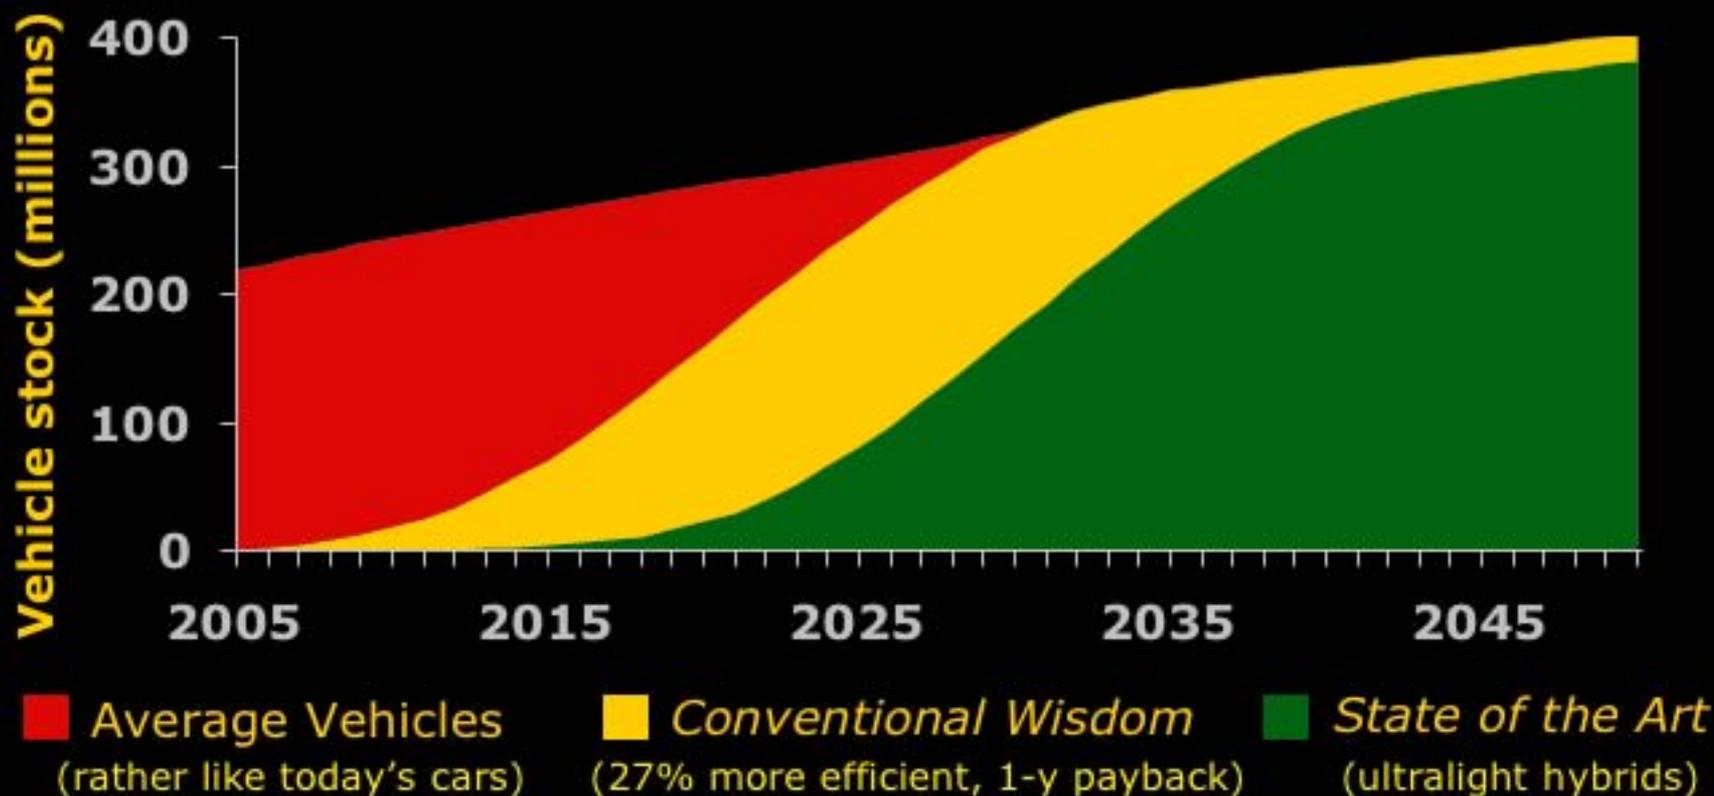

Adding smart government procurement and Golden and Platinum Carrot competitions increases market capture pulls *State of the Art* vehicles to an earlier starting date

# Mobilization: Accelerating Change

4.5 Mbbbl/d saved, \$391 billion in retail fuel savings

**90–100% State of the Art vehicles by 2040**

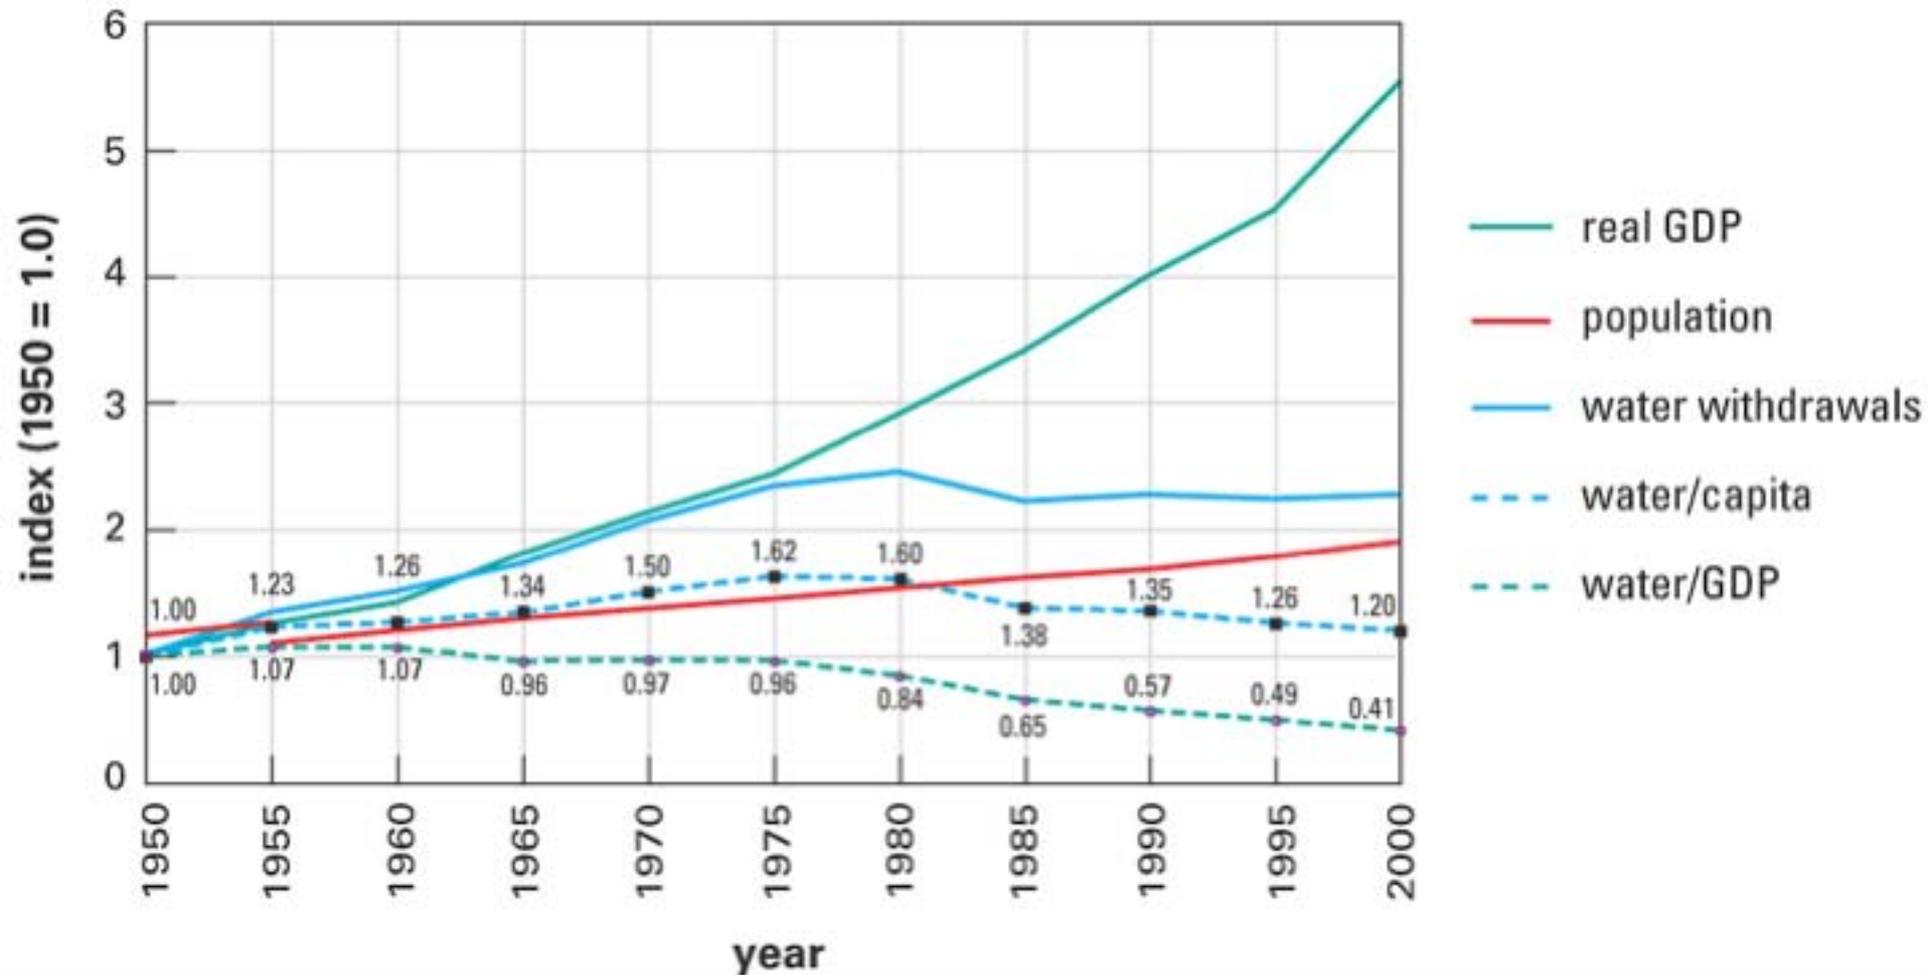

## Big, fast changes have happened

---

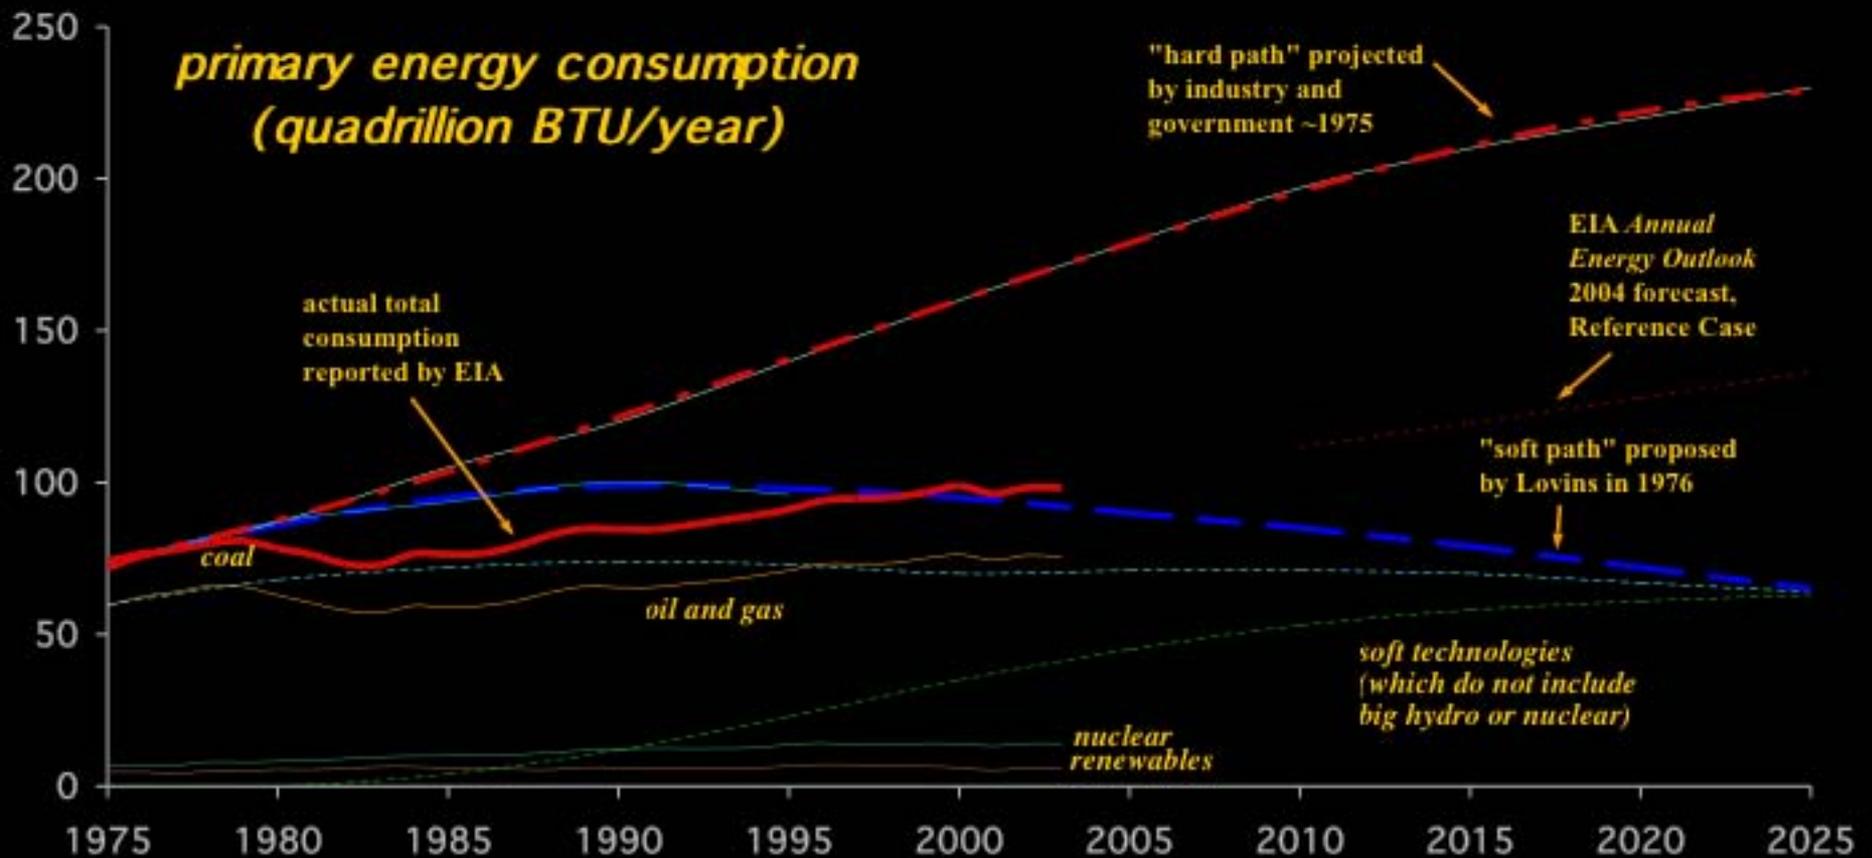

- ◇ U.S. automakers switched in **SIX YEARS** from 85% open wood bodies to 70% closed steel bodies—and in **SIX MONTHS** from making four million light vehicles per year to making the tanks and planes that won World War II
- ◇ Major technological transformations take **12–15 years** to go from 10% to 90% adoption
- ◇ The key is to get to the first 10% much faster!
- ◇ In 1977–85, U.S. cut oil intensity 5.2%/y—equivalent, at a given GDP, to a Gulf every 2.5 years
- ◇ If every 2025 light vehicle were as efficient as the best 2004 cars & SUVs, they'd save 2 Gulfs' worth

# Analogy: did anyone notice the U.S. water-efficiency revolution?

# U.S. energy/GDP already cut 43%, to very nearly the 1976 "soft path"

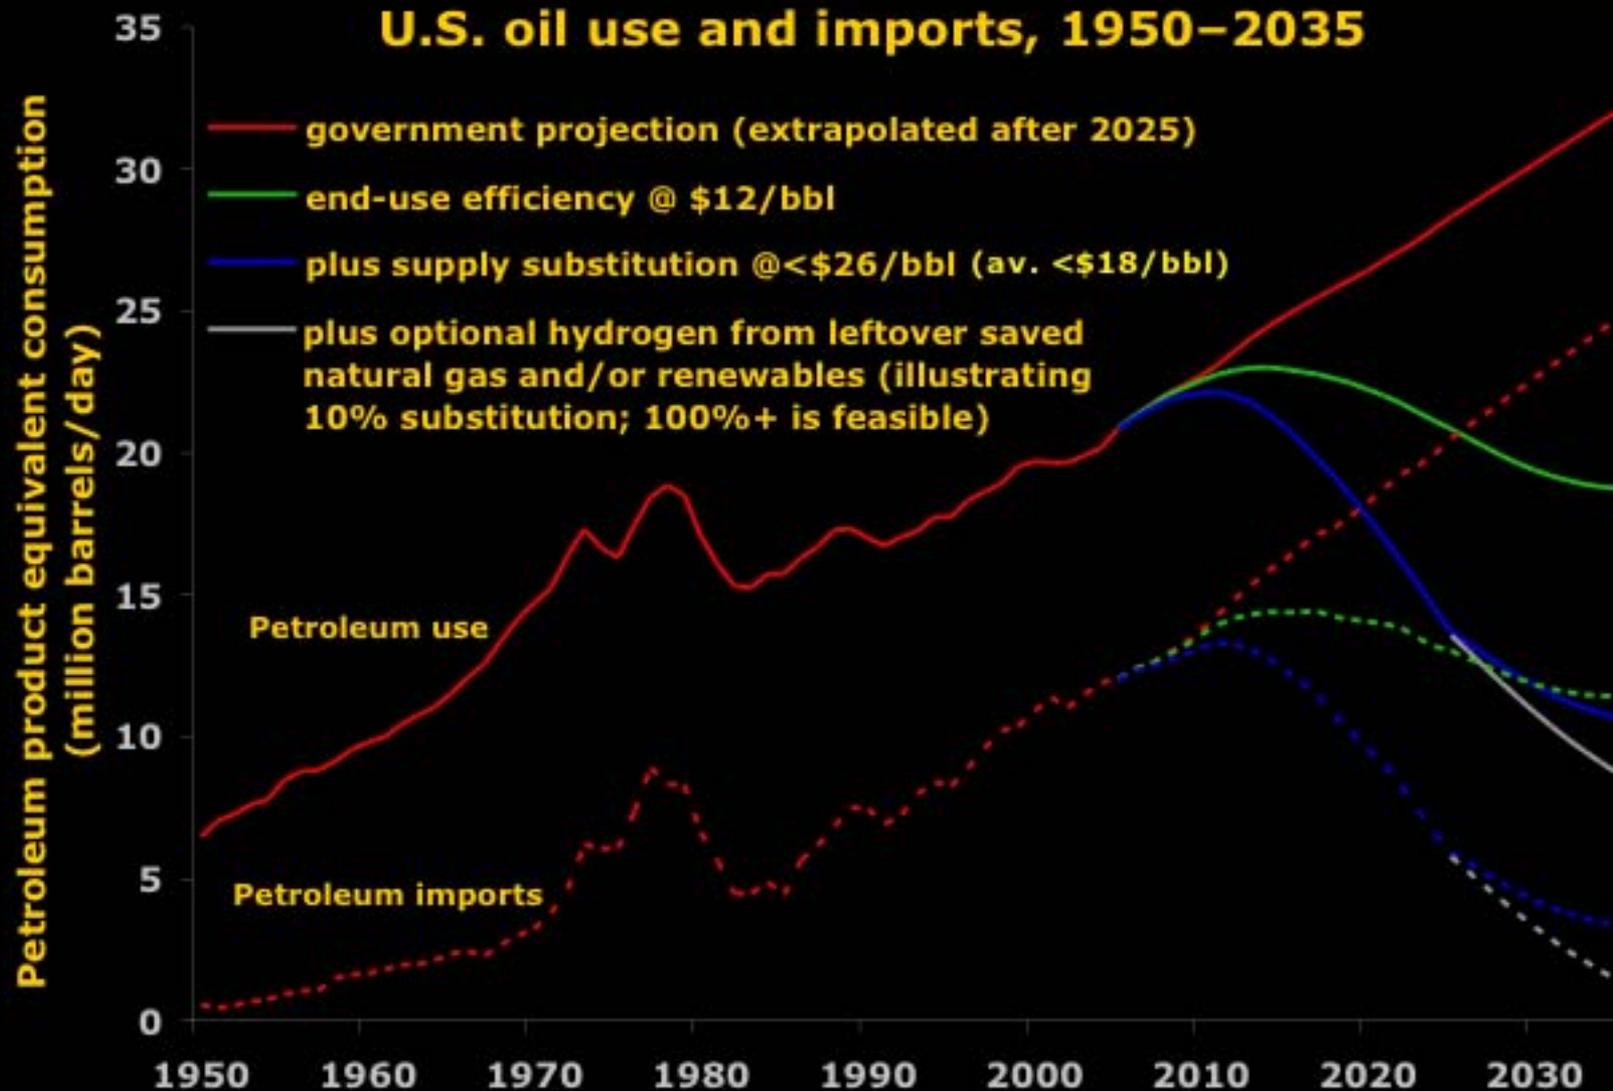

...but that just scratches the surface, especially for oil

# A profitable U.S. transition beyond oil

## U.S. oil use and imports, 1950–2035

# Why should you care enough to act?

**What are we waiting for?  
Let's play the Oil Endgame to win.**

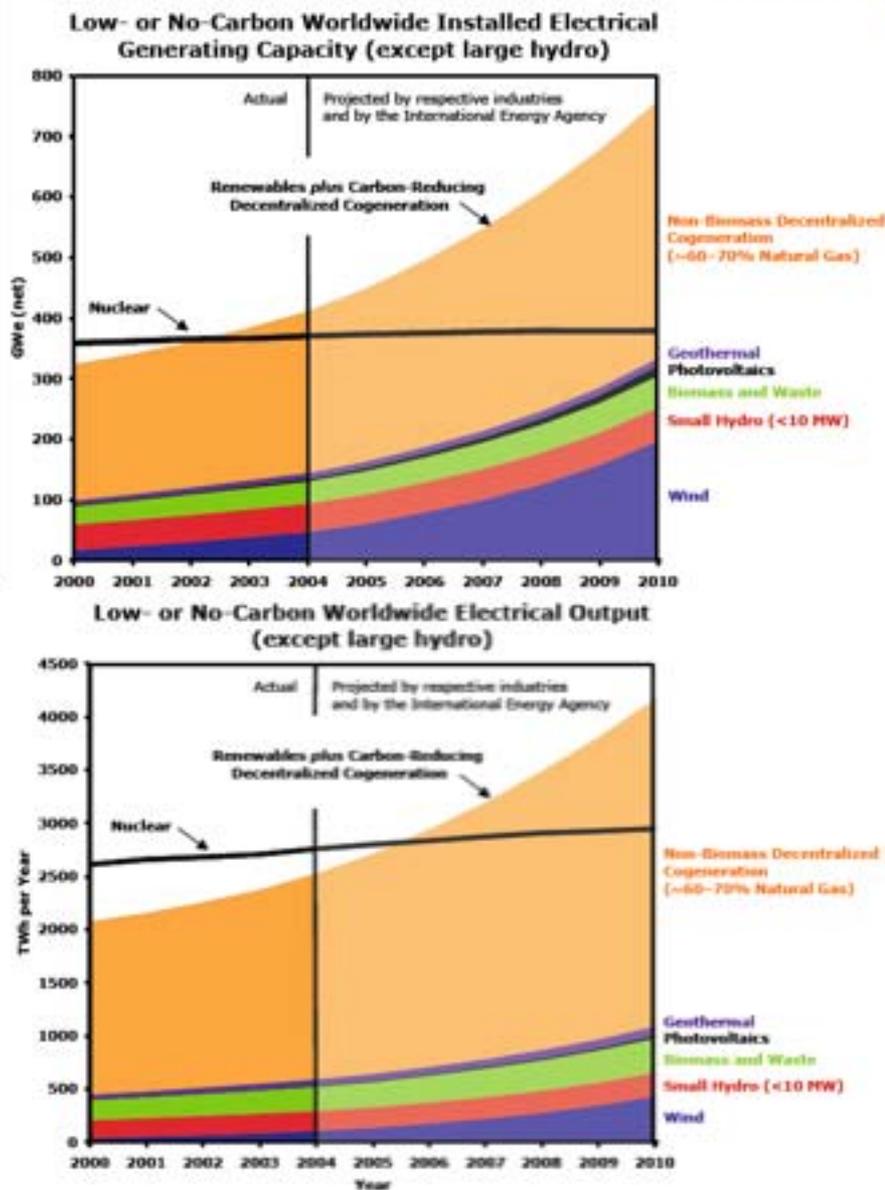

***Free download from  
[www.oilendgame.com](http://www.oilendgame.com)***

## (What about nuclear power?)

---

- ◇ Unfinanceable in the private capital market; the few orders are all in centrally planned electricity systems
- ◇ That's because it's fundamentally uncompetitive
  - A new delivered nuclear kWh costs ~10–30x more than end-use efficiency, ~5–10x more than gas-fired cogen/trigen, & ~2–3x more than windpower: the IAEA, MIT, Harvard, & Chicago studies all ignored all these, and compared nuclear with the wrong competitors
  - Regulatory change, new reactor types, H<sub>2</sub>, C tax won't save nuclear
  - The three fatal competitors are getting even cheaper...2 more soon
- ◇ Irrelevant to U.S. oil problem: <3% of el. is oil-fired (0.3% distillate), <2% of U.S. oil makes el., both ↓
- ◇ Red herring, died of an incurable attack of mkt forces
- ◇ That's good...it can belatedly help block proliferation
- ◇ Big opportunity cost: nuclear spending harms climate

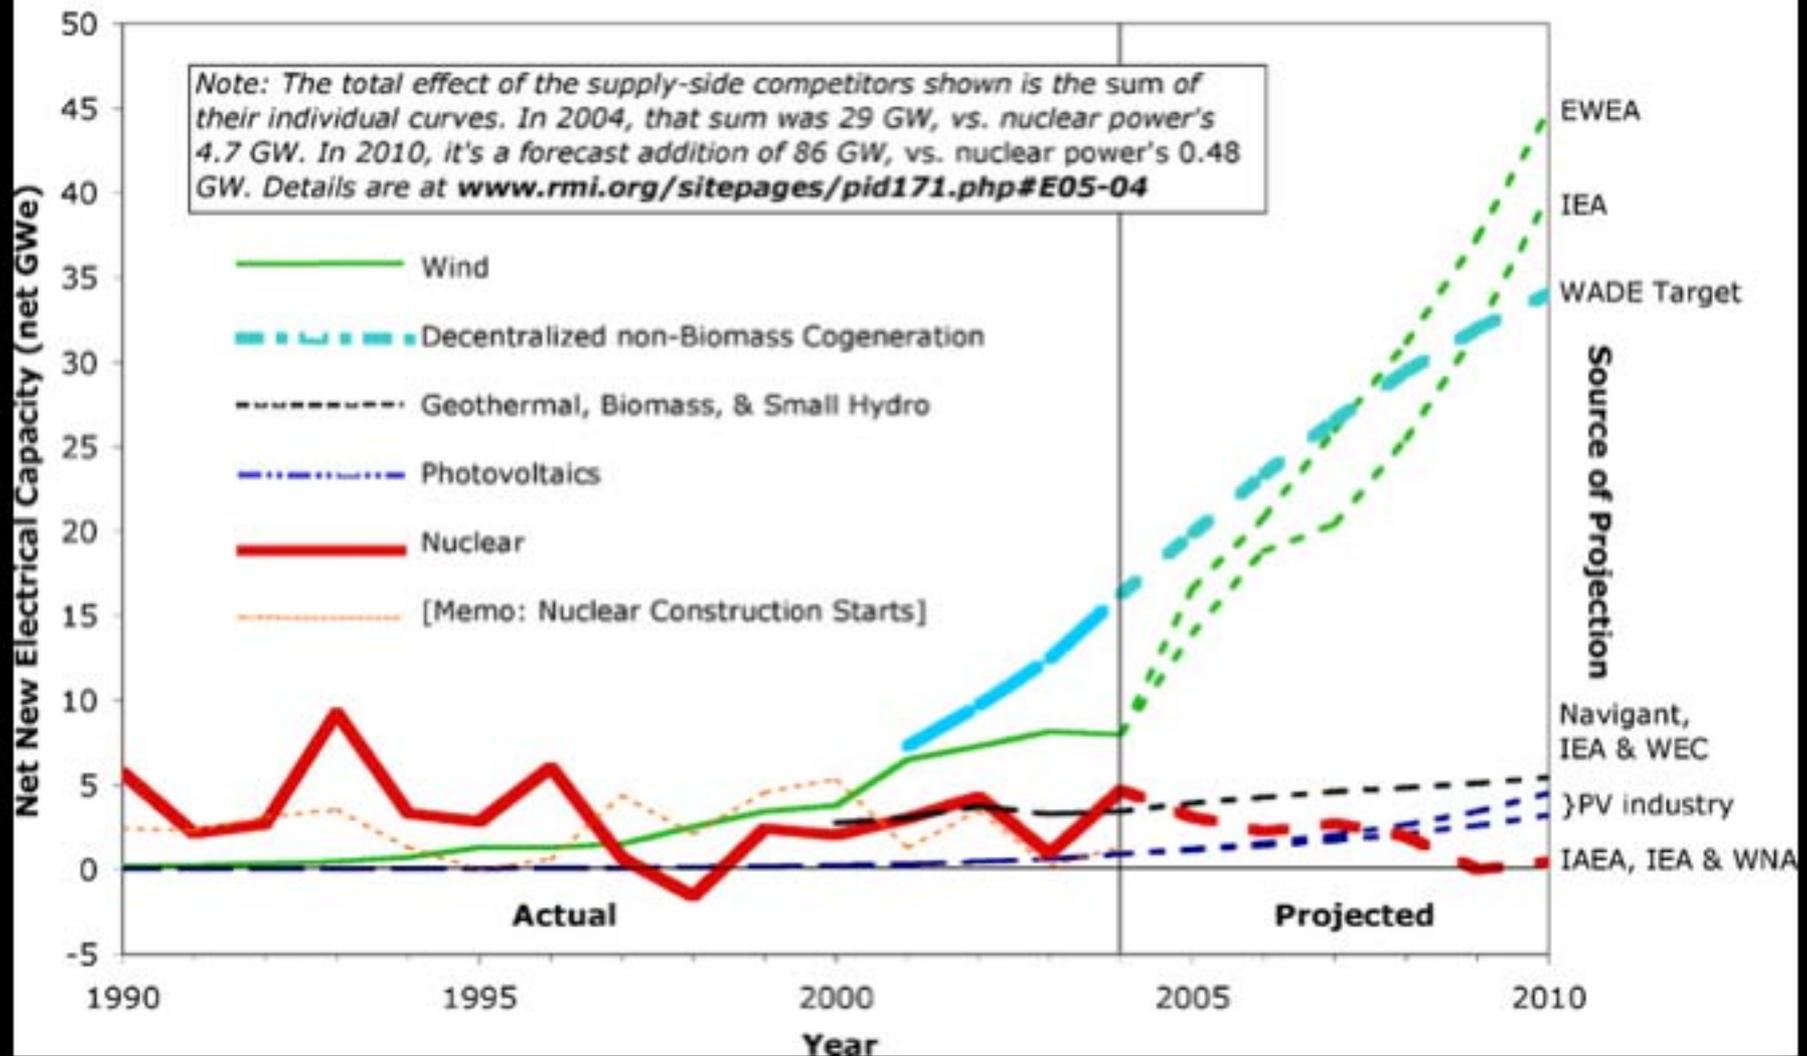

# Decentralized generators surpassed world nuclear capacity in 2002, its output in 2005

- Two-thirds of decentralized new capacity is combined-heat-and-power, ~60-70% gas-fired
- The rest is renewable (hydro only if <10 MW<sub>e</sub>)
- These low- or no-carbon options added in 2004 5.9× as much capacity & 2.9× as much output as nuclear
- Their projected 2010 cap-add is ~177× nuclear's
- Demand-side resources bigger...but no data kept!

# Nuclear's decentralized supply competitors, supposedly small and slow, already beat it

**Global Additions of Electrical Generating Capacity by Year and Technology: 1990–2004 Actual and 2005–2010 Projected**

## **Nuclear power's supposedly rosy prospects are bad and worsening**

---

- ◇ The claim that decentralized competitors are small and slow is rebutted by actual market behavior
- ◇ The demand- and supply-side competitors are bigger, faster, and improving far faster
  - New reactor types (pebble-bed,...) won't help materially
- ◇ The market is also starting to value 207 "distributed benefits" that make micropower ~10x more valuable
- ◇ Featuring and favoring nuclear power in national energy policy has historically harmed its advance
- ◇ Competitive power markets and transparent political choices, both spreading, destroy nuclear's prospects
  - It's never been bid into a power auction, because it'd lose
- ◇ Building nuclear plants earns only a few b\$/y of revenue and no profit—hardly a serious business—vs renewable power's \$28b/y revenue and significant profit; education & infrastructure are dwindling

## **Nuclear “revival”: the U.S. industry’s proposed conditions**

---

- ◇ Taxpayers pay first \$1.8b + 20% of the rest of the capital cost + all licensing + R&D costs
- ◇ Taxpayers guarantee the loans and guarantee to buy all the power at above-market prices
- ◇ Current large operating subsidies + 1.8¢/kWh
- ◇ Liability capped forever; most lesser liability evadable by shell companies
- ◇ All waste taken for small fee, w/penalty if late
- ◇ All offsite security costs borne by taxpayers
- ◇ Substantive public participation eliminated, local objections overridden, big risks ignored (such as plausible and threatened terrorism)
- ◇ In short, taxpayers take all remaining costs and risks; promoters pocket any upside

# Nuclear power: policy questions

---

- ◇ Why divert public resources from market winners to the big market loser?
- ◇ Why pay a premium to incur its problems?
- ◇ Why incur the opportunity cost of buying less climate solution per dollar (and slower)?
  - Why not use normal marginal cost/benefit comparison?
- ◇ If you think “we need everything” (no choices):
  - What’s your analytic basis for that belief?
  - How do you propose to pay for buying everything?
  - Since different choices have different prices, how do you avoid the “Chinese restaurant menu problem”? (Pick one item from each section, spend half your money on shark’s-fin soup, be unable to afford rice, go away hungry)

## What happens with competitive bidding?

---

- ◇ California's 1982–85 fair bidding with roughly equal subsidies elicited, vs. 37-GW 1984 load:
  - 23 GW of contracted electric savings acquisitions over the next decade (62% of 1984 peak load)
  - 13 GW of contracted new generating capacity (35% of 1984 load), most of it renewable
  - 8 GW (22%) of additional new generating capacity on firm offer
  - 9 GW of new generating offers arriving *per year* (25%)
  - Result: glut forced bidding suspension in April 1985
- ◇ U.S. 1979–85: more new capacity ordered from small hydro and windpower than from coal and nuclear plants, excluding their cancellations (>100 GW)...yet nuclear got (in FY1984) 24x the subsidy/kWh that nonhydro renewables got, and doesn't face their obstacles to fair interconnection

# The next electric revolution: efficient and distributed

- ◇ In late 1980s, full best retrofit could save ~3/4 of U.S. el. @ av. ~0.6¢/kWh ('86\$)
- ◇ Key technologies & delivery methods now far cheaper
- ◇ Biggest revolution: whole-system design integration yields *expanding* returns to efficiency investment
  - See *Encyc. of Energy* 2004 article; [www.natcap.org](http://www.natcap.org)
- ◇ Distributed electricity is often competitive *now*—even PVs when integrated with demand-side management
- ◇ But commodity ¢/kWh omits key “distributed benefits”
  - *Small Is Profitable: The Hidden Economic Benefits of Making Electrical Resources the Right Size* ([www.smallisprofitable.org](http://www.smallisprofitable.org), 2002), an *Economist* Book of the Year
  - 207 distributed benefits boost typical economic value *by* ~10x; the biggest benefits come from financial economics, then el. engineering
  - “Cleaner Energy, Greener Profits” ([www.rmi.org](http://www.rmi.org), 2001) shows fuel cells can often be profitably applied even at \$2,000–3,000/kW

# The U.S. oil problem

---

- ◇ Americans use 26%, produce 9%, and own 2–3% of the world's oil, so we can't drill our way out
- ◇ Fungible in world market; issue is use, not imports
- ◇ The next barrel is cheaper abroad than at home
- ◇ Only three solutions in a market economy
  - Protectionism
  - Trade
  - Substitution
- ◇ Three basic approaches to oil strategy
  - Ostrich
  - Drill and kill
  - Innovate and revitalize—cheaper, safer, surer; our focus

## The wider context: eight keys to energy security

---

- ◇ Remove climate change's risks and costs
- ◇ Make electric blackouts impossible by design
  - Efficiency & load response, distributed generation, renewables
  - More and bigger powerlines are part of the problem
- ◇ Continue the market's phaseout of nuclear power
  - Removing ambiguity unmasks proliferators
- ◇ Apply to natural gas what we've learned about el.
  - Efficiency & load response; avoid overshoot into costly LNG
- ◇ Evolve the whole energy system toward resilience
  - Efficient, dispersed, diverse, renewable (*Brittle Power* thesis)
- ◇ Get off oil—systematically, rapidly, and profitably
- ◇ Same for DoD, now the world's largest oil buyer
- ◇ Change the energy policy process so it works (NEPI)

## Our economic framework (2000 \$)

- ◇ EIA 2025 Refiner's Acquisition Cost (RAC) is \$26/bbl
- ◇ We compare all costs w/ RAC on the *short-run* margin
- ◇ We omit all externalities; many are important
  - The market values oil-price volatility at ~\$3.5/bbl over next 5 y
  - Some upstream and downstream capex to 2025+ is avoidable
  - Military: U.S. pays ~2–3× as much for peacetime readiness costs of forces whose main mission is Gulf intervention as for Gulf oil; could cost ~\$10/bbl (econometric) or several times that much; even so, the market currently attaches a ~\$5-12/bbl security-risk premium
  - Nonmilitary federal budget net subsidies: ~\$2–3/bbl and rising
  - Environmental and climatic: NAS/NRC ~\$11/bbl but very uncertain
  - Major costs to foreign relations, peace, development,...
- ◇ We count rebound for light vehicle VMT, but net the effect of sustaining gasoline tax revenues & of IHS
- ◇ Transparent: all #s from hand calculator/spreadsheets
- ◇ All discounting is at 5%/y real (OMB uses 3.2%/y)

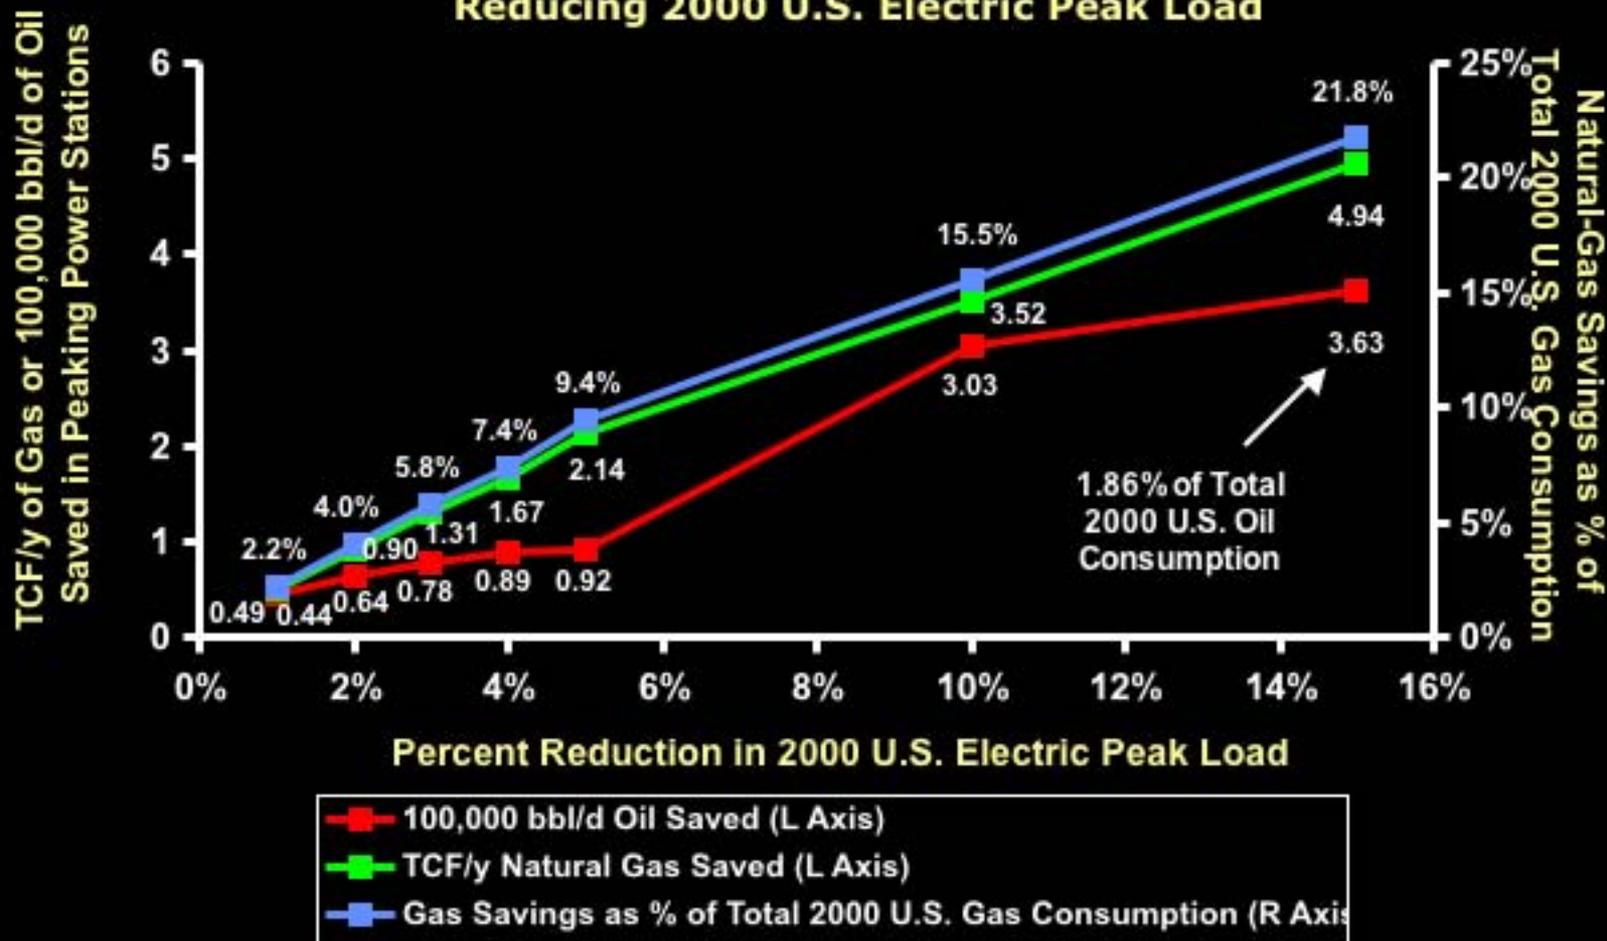

## No general-equilibrium calc, but if savings drop RAC far below EIA's \$26/bbl...

- ◇ Since we save half the oil, the value of that saving will drop by the same amount as the cost of the other half—a wash (assuming no change in energy taxation)
- ◇ Our savings might decrease at low oil prices, but there are important countervailing effects:
  - Half our SOA savings cost <\$12/bbl on the short-run margin; the average of *all* SOA savings costs <76¢/gal *retail* gasoline
  - Our SOA savings are conservatively calculated, assume only technologies being commercialized now, and omit many options
  - Once installed, efficiency techniques don't get uninstalled—our savings are technological/permanent, not behavioral/temporary
  - If the U.S. fully adopts our recommendations, that's only 1/4 of the world market, diluting 4:1 the effect on world market price
  - While the U.S. & others save, low- & mid-cost reserves outside the Gulf are being depleted, increasing OPEC's market power
  - EIA may understate demand growth in China, India, etc.
- ◇ So we don't think lower oil prices (resulting from the wild success and fast, wide adoption of our recommendations) are likely to change our results significantly... though that'd be a nice problem for the world to have

# How to return U.S. gas prices to ~\$2-3 for ~3-5 y: ~5% electric load management/demand response

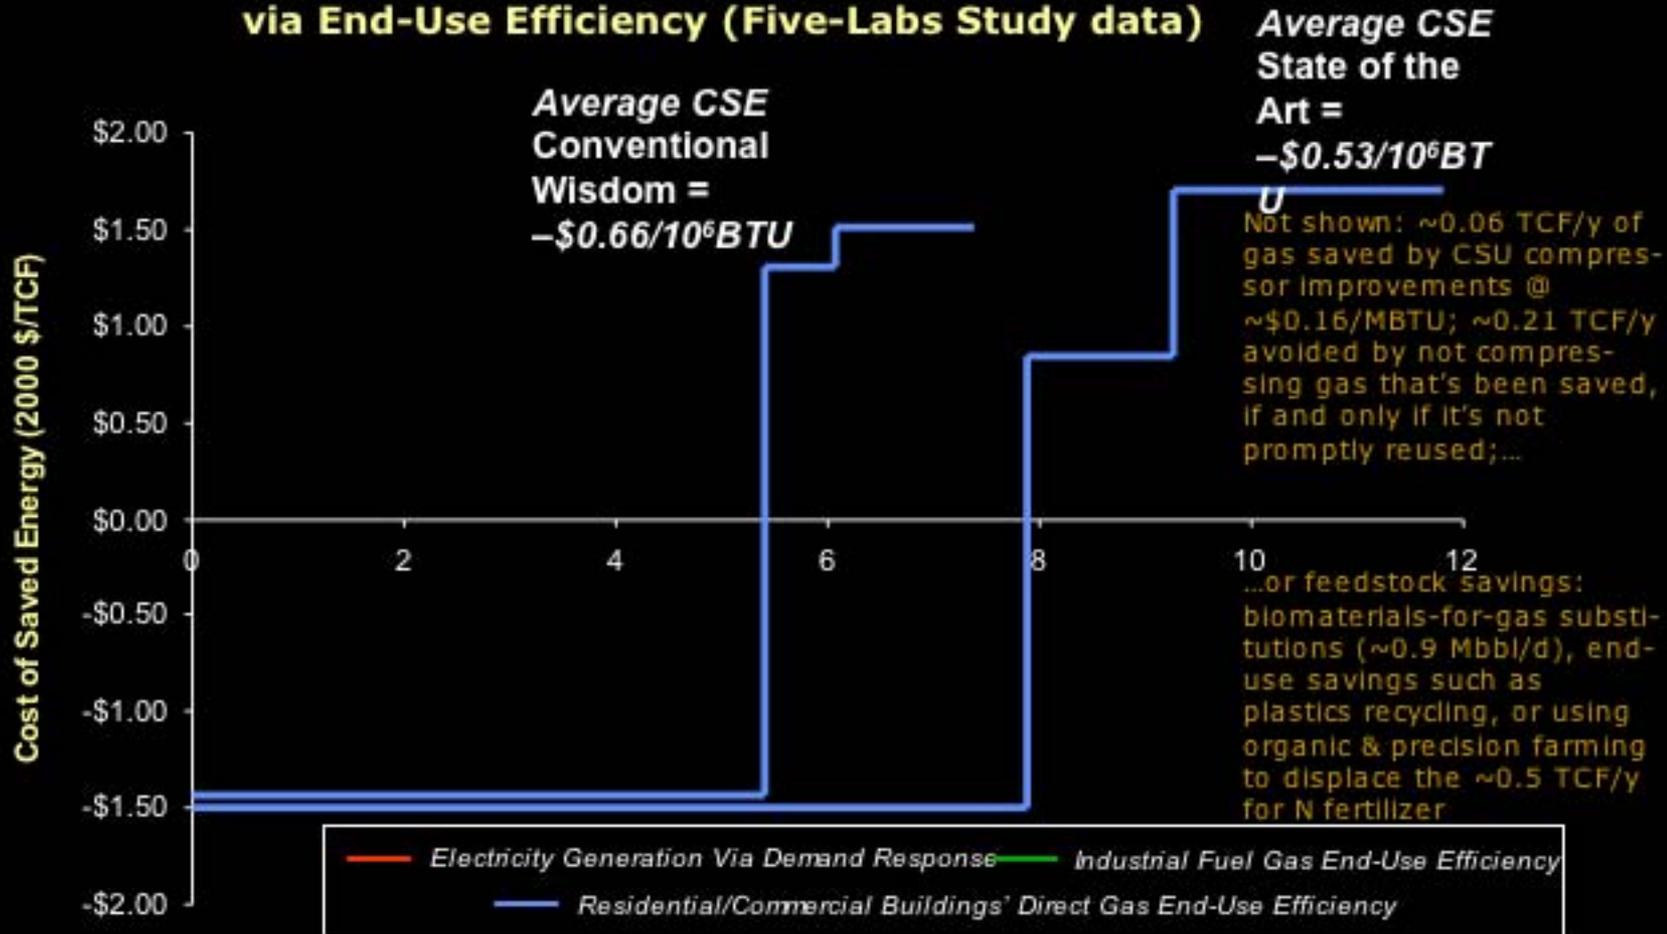

Natural Gas Oil Savings Resulting From Reducing 2000 U.S. Electric Peak Load

Note: This August 2003 analysis by Kyle Datta and his colleagues at Rocky Mountain Institute uses the entire published plant-by-plant inventory, and assumes economic dispatch. There are unresolved minor uncertainties associated with dual-fueled peaking plants, interregional power flows, and transmission constraints. Copyright © Rocky Mountain Institute 2003. # Saving U.S. natural gas

## Potential Savings of U.S. Natural Gas (TCF/y) via End-Use Efficiency (Five-Labs Study data)

Five-Labs (CEF) Study's conservative costs of saving electricity, less avoided onpeak gen. cap. & deferred grid cap., saves electricity at  $-1.6\text{¢}/kWh$ . Converted at the appropriate heat rates, that can save 25% of total 2025 gas use at  $-\$1.5/10^6 BTU$ .

# Substituting saved gas for oil if relative burner-tip prices unknown

Potential 2025 Substitution of Saved Natural Gas for Suitable Uses of Oil (Mbbbl/d)

# **\$180 billion total investment for >\$150 billion *annual return***

---

- ▶ **The \$180 billion investment over 10 years is small compared to our other choices: \$18 billion a year vs.:**
  - Oil imports (largely wasted, money lost)—**\$18 billion every 5–6 weeks**
  - **\$40 billion a year** for Homeland Security, some oil-related
  - **\$50+ billion a year** in peacetime military readiness for Gulf intervention (~2–3× what we pay to *buy* oil from the Gulf); increasing oil-protection burdens on all Commands
- ◇ **>\$150 billion a year in societal value by 2025**
  - **\$133 billion a year** in lower oil consumption (@ USEIA's \$26 a barrel)
  - **\$10–30+ billion a year** in military fuel logistics costs saved
  - **\$0.5 billion a year** in unnecessary agricultural subsidies
  - **\$11 billion a year** in carbon credit value
- ▶ **What's it worth to eliminate worries about oil's insecurity, volatility, and depletion? To regain the moral high ground? To have a safer world?**

# Today's concept vehicles will go mainstream, integrating ultralight, ultra-low-drag, and advanced-propulsion

CARS: save 69% at 57¢/gal

PLANES: save 20% now (787), 45% @ 46¢/gal

Surprise: ultralighting is **free** — offset by simpler automaking and the 2x smaller powertrain!

155 mph, 94 mpg

TRUCKS: save 25% free, or 65% @ 25¢/gal

BLDGs/IND: big, cheap savings; often *lower capex*

Technology is improving faster for efficient end-use than for energy supply

# The future is already here: today's concept vehicle approaches will be tomorrow's mainstream ...

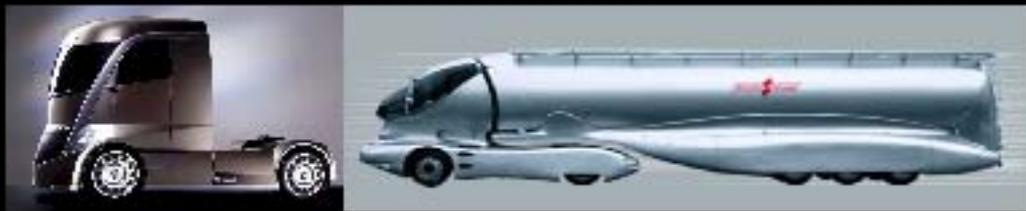

CARS: save 69% at 57¢/gal

PLANES: save 20% free (787), 45% @ 46¢/gal

TRUCKS: save 65% @ 25¢/gal

BLDGS/IND: big, cheap savings; often lower capex

Technology is improving faster for efficient end-use than for energy supply

# Two ways to drive 12 km in the city

"Avcar"  
production  
platform  
(U.S. 1994  
average)

One Liter  
Fuel

15% Efficient Conventional  
Engine & Driveline (fuel to  
wheels)

2-4% used for  
Accessories

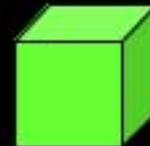

85% lost  
as heat  
and  
emissions

Aero Drag  
 $C_D A = 0.76 \text{ m}^2$

Rolling Drag  
 $r_0 M + f = 200 \text{ N}$

Braking  
 $M = 1443 \text{ kg}$   
0% Recovered

Near-term  
Hypercar  
with interior space  
equivalent to 1994  
Avcar

0.33 L  
Fuel

24% Efficient Complete  
Hybrid Driveline (fuel to  
wheels)

0.5-1% used  
for Accessories

76% lost  
as heat  
and  
emissions

Aero Drag  
 $C_D A = 0.42 \text{ m}^2$

Rolling Drag  
 $r_0 M + f = 69 \text{ N}$

Net Braking  
 $M = 600 \text{ kg}$   
48% Recovered

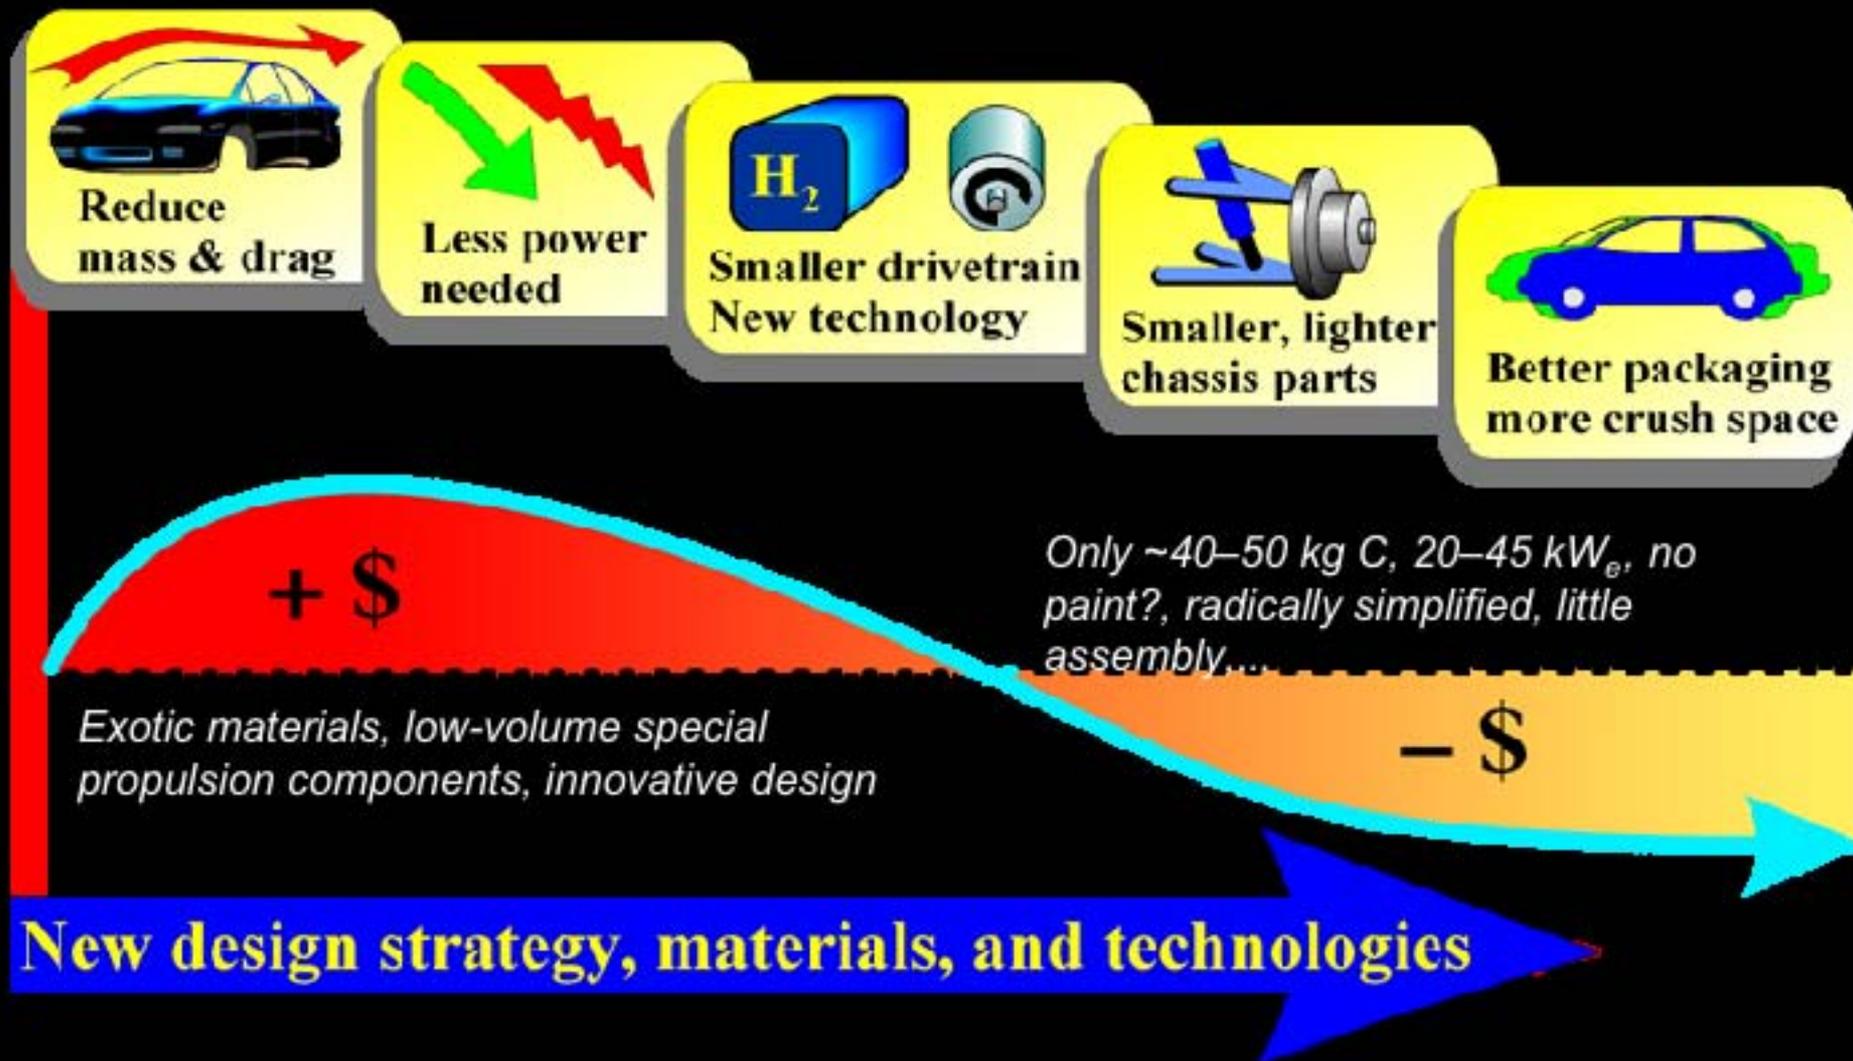

In highway driving, efficiency *falls* because there is far more irrecoverable loss to air drag (which rises as  $v^3$ ) and less recoverable loss to braking.

# Saving >80% of fuel...incidentally

---

- ◇ Conventional design: save fuel as specific goal
- ◇ Trade off and compromise other design goals (size, cost, performance, perhaps safety)
- ◇ Rely on government intervention—efficiency standards, gasoline taxes, subsidies, mandates—to induce people to buy those less attractive cars
- ◇ Hypercar design: make the car *superior*, yet comparably priced, so people will want to buy it (like buying digital media instead of vinyl phonograph records)
- ◇ This also happens to save even more fuel
- ◇ Ultralight, ultra-low-drag triggers a long series of “virtuous circles”; then hybrid drive can make the car lighter, simpler, cheaper
- ◇ Mass savings snowball... nonlinearly

# Decompounding mass and complexity also decompounds cost

# Affordable cars via costly materials

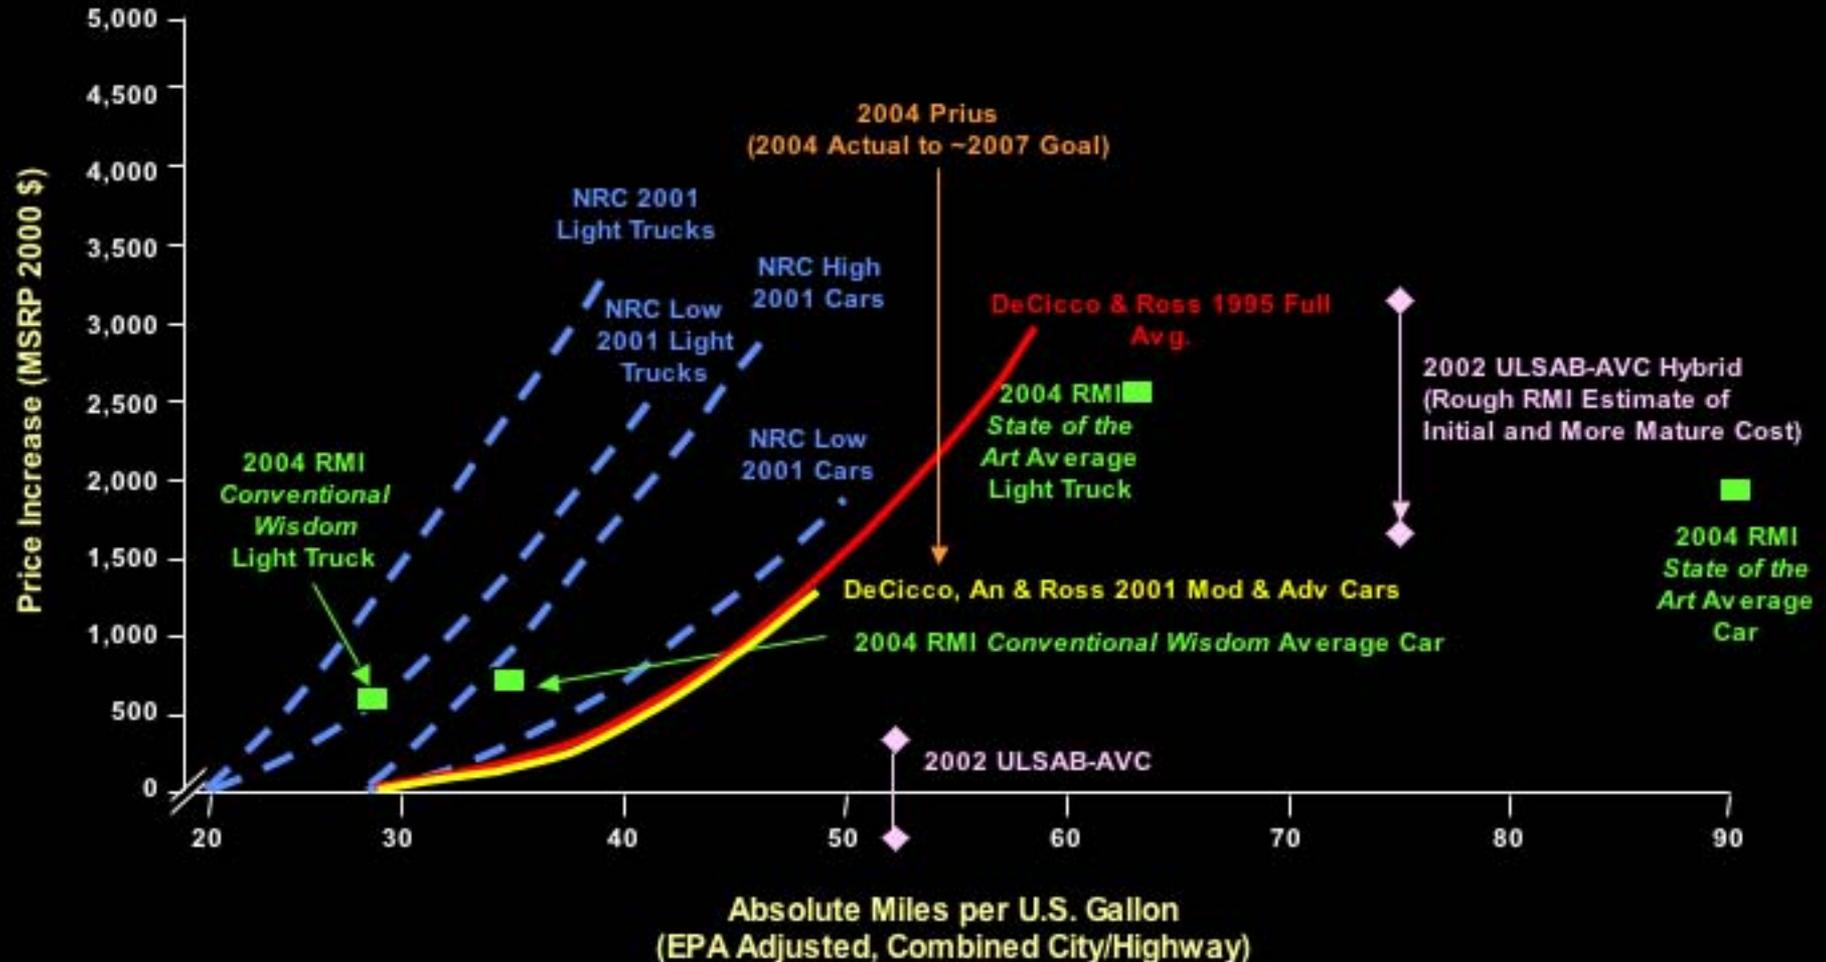

---

- ◇ Conventional design: stamped/welded steel
- ◇ Cheap material/kg, but costly to manufacture
- ◇ Two years to design & make ~1,000 steel dies
- ◇ High capital intensity, breakeven volume, and financial risk per model
- ◇ Long product cycle time increases risk
- ◇ Uninviting risk/reward profile
- ◇ Hypercar design: molded/glued advanced composites
- ◇ Costly material/kg, but we all buy cars by the car, not by the kg; offset by mfg.
- ◇ <20 dies, can be soft tooling
- ◇ Self-fixturing assembly
- ◇ Many-fold less capital, assembly, parts, ?time
- ◇ Small propulsion system
- ◇ Very low breakeven volume and risk per model
- ◇ Not sumo but aikido

# Ultralight-but-safe light vehicles open a new, vast, roughly free design space

All Vehicles Shown in Green are Adjusted to EIA's 2025 Acceleration Capability for That Class of Vehicle  
RMI's 2004 Average Vehicles are for EIA's 2025 Sales Mix

## **Detroit must act to avoid the "Creative Destruction" fate**

---

- ▶ **U.S. share for light vehicles steadily declining; SUVs last profit bastion; Big 3 mkt. capitalization < Toyota**
- ▶ **Consumers want provide comfort and safety without guilt—but won't pay much more**
- ▶ **Breakthrough vehicles will be a disruptive product. Do we have the management vision this shift requires?...**
- ▶ **...or will we fall short, and succumb to Schumpeter's "creative destruction"?**
- ▶ **The question is who will make them: the U.S. or Japan (or possibly Europe and China and India)?**
- ▶ **If we fail to act, our car companies, and the industrial cluster that depends on them, could fade away**
- ▶ **We can import efficient cars to replace foreign oil...or make the cars ourselves and import neither**

## Seattle/Chicago has already bet on efficiency: Boeing vs. Airbus

---

- ▶ The competitive battle for the next generation of commercial aircraft features the efficient 787 (~20% less fuel, ~same price) vs. A380
- ▶ Disruptive change is more than technology, it's also new business models
- ▶ Boeing is betting on a change in the airline business model to point-to-point (discounters) vs. fortress hubs (legacy airlines)
- ▶ Since the market cap of U.S. discount airlines is already 4x that of the 6 U.S. legacy airlines, Boeing may have made a good bet

## Rapid, profitable **H<sub>2</sub> transition** (RMI, NHA paper, April 1999, [www.rmi.org](http://www.rmi.org))

---

- ◇ Put fuel cells first in buildings for co-/trigen + UPS
  - Fuel with natural-gas reformers (or off-peak electrolyzers)
  - Big market — buildings use 2/3 of US electricity
- ◇ Meanwhile introduce H<sub>2</sub>-ready Hypercar<sup>®</sup> vehicles
  - Fleets (return nightly to the depot for refueling)
  - General market: start with customers who work in or near the buildings that by then have fuel cells
    - > Use buildings' hydrogen appliances for refueling
      - Sized for peak building loads that seldom occur
    - > Sell kWh and ancillary services to grid when parked
      - Marginal investment in H<sub>2</sub> compression/fueling, grid connection, & more durable fuel-cell stack is modest
    - > First ~2M earn back much/most of cost of car ownership
      - U.S. full-fleet potential ~5–10 TW, ~6–12× grid capacity

## Rapid, profitable **H<sub>2</sub>** transition (2)

---

- ◇ Meanwhile, hydrogen appliances get cheaper, so put them outside buildings too
  - At filling stations — a much better business than gasoline
    - > Use two ubiquitous, competitive retail commodities — CH<sub>4</sub> and el. — and play them off against each other
    - > Use just the offpeak distribution capacity for gas and electricity that is already built and paid for
    - > Mainly reformers: electrolyzers favored only at high volume, small unit scale, and cheap offpeak kWh
    - > ~10<sup>3</sup> reformers @ US\$6/GJ gas beat \$0.24/L in \$/km
  - Scaleable, modular, big economies of mass-production; carbon sequestration may scale down to the forecourt
  - As both hydrogen and direct-hydrogen fuel-cell vehicles become widespread, bulk production and central distribution of hydrogen becomes practical and may be justified

## Rapid, profitable **H<sub>2</sub>** transition (3)

- ◇ **≥2 proven, cost-effective, climate-safe methods**
  - Reform natural gas at the wellhead and reinject the CO<sub>2</sub>
    - > Reforming (6–8% of U.S. gas now) & reinjection are mature
    - > Potentially three profit streams: H<sub>2</sub>, +CH<sub>x</sub>, -C
    - > Strong industry interest (BP, Shell, Statoil), 200-y resource
  - Electrolyze with climate-safe electricity
    - > Greatly improves ecs. of renewable electricity, bec. H<sub>2</sub>-to-wheels is ~2–3× more efficient than gasoline-to-wheels
      - Even U.S. gasoline (\$0.33/L) is equivalent at the wheels to \$0.09–0.14/kWh electricity with a proton attached to each electron — so run dams in “Hydro-Gen” mode, shipping compressed hydrogen instead of kWh (a value-added product instead of the electron commodity)
      - H<sub>2</sub> storage makes wind/PV power firm and dispatchable
- ◇ **Probably more: coal, oil, various renewables,...**

# Demonstrating hydrogen vs. gasoline safety

Side-by-side worst-case test of deliberate leakage of hydrogen (left: 1.54 kg = entire tank volume in ~100 s, 185 MJ) compared with a rather small leak of gasoline (right: 1.6-mm hole, 2.37 L, 74 MJ). The hydrogen flame is visible because sodium in particulates naturally present in the air. This test assumed a leak at the tank's Pressure Relief Device (yielding the fastest possible loss) *and* failure of the standard H<sub>2</sub> sensor, pressure-drop, and flow-comparator shutoff devices. A hydrogen leak *under* a fuel-cell vehicle designed to standard protocols would require failure of those three safety devices and of the fuel line.

M.R. Swain, "Fuel Leak Simulation," [www.eren.doe.gov](http://www.eren.doe.gov), 2002.

3 s: Ignition. H<sub>2</sub> @ 28 L/min, gasoline @ 0.68 L/min

60 s: H<sub>2</sub> flow subsiding; max 47° C on rear window, 19.4° C on tray behind rear seat. Zooming in on gasoline car...

90 s: H<sub>2</sub> plume nearly stopped.

140 s: Gasoline-car interior alight. Tires later burst.

# Hydrogen-ready cars + integration with buildings = fast, profitable H<sub>2</sub> transition

(A.B. Lovins & B.D. Williams, NHA, 1999, [www.rmi.org](http://www.rmi.org))

---

- ◇ No technological breakthroughs required (new storage tech or onboard reformers); as soon as durable and cheaper fuel cells arrive, fuel-cell cars can be marketed profitably, many years earlier than would be possible with inefficient vehicles
- ◇ Staged deployment based on building & gas-station reformers
- ◇ Meanwhile, engine or engine-hybrid Hypercar<sup>®</sup> vehicles can save most of the oil & CO<sub>2</sub> (3.5 L/100 km midsize SUV, vs 2.1 with H<sub>2</sub> FC)
- ◇ It doesn't matter whether stacks first become durable (favoring buildings) or cheap (favoring cars); whichever happens first will accelerate both markets
- ◇ No need for new liquid-fuel infrastructure (methanol, ultrapure gasoline,...), liquid H<sub>2</sub>, or costly central H<sub>2</sub> production/distribution
  - See "Twenty Hydrogen Myths," 2003, [www.rmi.org](http://www.rmi.org), *Intl J Hydr En* forthcoming
- ◇ Integrating mobile and stationary deployment makes the transition profitable at each step (>10%/y real return)

## Six hydrogen surprises (see "20 Hydrogen Myths," [www.rmi.org](http://www.rmi.org))

---

- ◇ >2/3 of fossil-fuel atoms burned today are H<sub>2</sub> — we only need to get rid of the last 1/3 (the carbon)
- ◇ Natural gas use won't go up much, may go down
- ◇ Hydrogen will need less capital than gasoline does
- ◇ Hydrogen would reduce drivers' fuel cost per km
- ◇ Hydrogen is more profitable for HC companies
- ◇ Hydrogen needs superefficient cars a lot more than they need hydrogen—but once you have them, the business case for producing the H<sub>2</sub> becomes robust
- ◇ Just Dakotas windpower could make enough H<sub>2</sub> (50 MT/y, = today's world H<sub>2</sub> production) to fuel all U.S. highway vehicles if they're profitably efficient

# Platform physics is more important than powertrain—and is vital to its economics

- ◇ Cars can run clean IC engines on gasoline or NG ( $\approx 1\eta$ )
- ◇ Better ones using hydrogen in IC engines ( $\leq 1.5\eta$ )
- ◇ Still better ones using  $H_2$  in IC-engine hybrids ( $\sim 2.5\eta$ )
  - Ford "Model U" concept car...but tanks  $>4\times$  bigger (niche market)
- ◇ Better still: ultralight autobodies, low drag, Otto ( $3\eta$ )
- ◇ Power those platforms with IC-engine hybrids ( $4\eta$ )
  - Hypercar 5-seat carbon *Revolution* has the same  $m_c$  &  $C_D$  as 2-seat aluminum Honda *Insight*...*Insight*-engine hybrid version 3.5L/100km
- ◇ Best: put fuel cells in such superefficient bodies ( $5-6\eta$ )
- ◇ **The aim isn't just saving fuel and pollution**
  - Also strategic goals in automaking, plug-in power-plants-on-wheels, off-oil, primary fuel flexibility, accelerated transition to renewables,...
- ◇  **$H_2$  needs  $5\eta$  vehicles far more than vice versa**
- ◇  **$5\eta$  vehicles make robust the business case for providing the  $H_2$  that their fuel cells would need**

# State/regional policy opportunities

---

- ◇ Electric and natural-gas distribution utilities
  - Efficient use, aligned incentives; distrib. bens. ([www.smallisprofitable.org](http://www.smallisprofitable.org))
- ◇ Light vehicles
  - Revenue- and size-neutral feebates; shift registration/excise?
  - Smart procurement (aggregating state and local?)
  - Pay-at-the-pump insurance; shift tax from fuels to roads & driving
  - Fund initial dealer carrying charges/bonuses for superefficient cars
- ◇ Heavy trucks
  - Allow extra axle, 2-/3-trailer combos w/better brakes, 60 mph
  - Raise GVWR to EU norm (110klb), 14'H, 59'L
  - Require fuel-economy driver's ed
- ◇ Biofuels (integrate with general farm/ranch reform)
  - Procurement, labeling, detaxation?, ?bonds, totalflex vehicles
